47 21 **Abstract**
48
49

50 22 Africa is endowed with a diverse guild of small carnivores, which could benefit stakeholders
51 23 by providing ecosystem services while fostering conservation tolerance for carnivores. To
52
53

54 1
55
56
57
58
59

60
61
62 24 investigate the potential of small carnivores for the biological control of rodents within agro-
63
64 25 ecosystems, we assessed both the ecological and social landscapes within two rural villages in
65
66 26 the Vhembe Biosphere Reserve, South Africa. We employed a camera trapping survey
67
68 27 underpinned by an occupancy modelling framework to distinguish between ecological and
69
70 28 observation processes affecting small carnivore occupancy. We also used questionnaires to
71
72 29 investigate perceptions of small carnivores and their role in pest control. We found the greatest
73
74 30 diversity of small carnivores in land used for cropping in comparison to grazing or settlements.
75
76 31 Probability of use by small carnivores was influenced negatively by the relative abundance of
77
78 32 domestic dogs and positively by the relative abundance of livestock. Greater carnivore diversity
79
80 33 and probability of use could be mediated through habitat heterogeneity, food abundance, or
81
82 34 reduced competition from domestic carnivores. Village residents failed to appreciate the role
83
84 35 of small carnivores in rodent control. Our results suggest that there is significant, although
85
86 36 undervalued, potential for small carnivores to provide ecosystem services in agro-ecosystems.
87
88 37

86 38 1. Introduction

89 39 Rodents cause significant damage to crops in small-holder farms in Africa (Granjon and
90
91 40 Duplantier, 2009; Monadjem *et al.*, 2015; Singleton, 2010; Swanepoel *et al.*, 2017). Existing
92
93 41 rodent control is highly reactive and almost exclusively based on the use of rodenticides. This
94
95 42 heavy reliance on poisons has led to increasing problems with the development of behavioural
96
97 43 and physiological resistance, environmental contamination, and non-target poisoning (Buckle
98
99 44 and Smith, 2015). Ecologically-based rodent management (EBRM) is a term popularised more
100
101 45 than 20 years ago (Singleton *et al.*, 1999) with an aim to re-emphasize the importance of
102
103 46 understanding rodent biology and behaviour of different species as well as agro-ecological and
104
105 47 socio-economic contexts. While traditional rodent pest solutions emphasized over-reliance on
106
107 48 poisons, EBRM advocates less harmful and sustainable solutions such as biological control
108
109 49 through increasing ecosystem services of natural predation for pest control. Several studies
110
111 50 have shown that the adoption of EBRM strategies for rodent pest management can be highly
112
113 51 effective in reducing rodent damage whilst reducing farmer reliance on rodenticides (Brown *et*
114
115 52 *al.*, 2006; Jacob *et al.*, 2010). EBRM has recently gained traction in small-holder agro-

119
120
121 53 ecosystems in Africa (Massawe *et al.*, 2011; Monadjem *et al.*, 2015; Taylor *et al.*, 2012).
122
123
124 54

125
126 55 In smallholder agro-ecosystems, and many other modified landscapes, the removal of apex
127 56 carnivore species from most human inhabited areas of Africa may have facilitated increased
128 57 mesocarnivore abundance (Caro and Stoner, 2003; Prugh *et al.*, 2009; Ritchie and Johnson,
130 57 mesocarnivore abundance (Caro and Stoner, 2003; Prugh *et al.*, 2009; Ritchie and Johnson,
131 58 2009). Such increases might cause several ecological services or disservices to human
132 59 communities. For example, small carnivores such as the red fox (*Vulpes vulpes*) provide
134 60 valuable ecosystem services such as seed dispersal and potentially controlling populations of
135 61 small mammals, regulating their impacts on keystone plant species and threatened habitats in
137 62 Europe (Cancio *et al.*, 2017). In contrast, in Africa the importance of small carnivores around
138 62 Europe (Cancio *et al.*, 2017). In contrast, in Africa the importance of small carnivores around
139 63 small-holder farming systems is well-recognised in terms of human-wildlife conflict and
140 64 ecosystem disservices (Blaum *et al.*, 2009; Gusset *et al.*, 2009; Woodroffe *et al.*, 2005), but is
141 64 ecosystem disservices (Blaum *et al.*, 2009; Gusset *et al.*, 2009; Woodroffe *et al.*, 2005), but is
142 65 less understood in terms of potential ecosystem services (Roemer *et al.*, 2009). This is
143 65 less understood in terms of potential ecosystem services (Roemer *et al.*, 2009). This is
144 66 unfortunate as Africa has a rich small carnivore assemblage, which could provide key
145 67 ecosystem services to surrounding communities (Schuette *et al.*, 2013). Furthermore, the
146 67 ecosystem services to surrounding communities (Schuette *et al.*, 2013). Furthermore, the
147 68 relatively large number of small-sized farms and small settlement areas in sub-Saharan Africa
148 68 relatively large number of small-sized farms and small settlement areas in sub-Saharan Africa
149 69 (Lowder *et al.*, 2016) are interspersed within a mosaic of semi-natural habitat that can increase
150 70 human-wildlife conflict (Crooks, 2002; Lamarque *et al.*, 2009). As farm sizes in Africa are
151 70 human-wildlife conflict (Crooks, 2002; Lamarque *et al.*, 2009). As farm sizes in Africa are
152 71 likely to continue to decline and further fragment the landscape (Masters *et al.*, 2013), there is
153 71 likely to continue to decline and further fragment the landscape (Masters *et al.*, 2013), there is
154 72 a real risk of further natural habitat loss, trophic collapse and loss of potential ecosystem
155 72 a real risk of further natural habitat loss, trophic collapse and loss of potential ecosystem

167 79 *alba*), are able to control rodent pests in some in agricultural contexts. Recent research suggests
168 79 *alba*), are able to control rodent pests in some in agricultural contexts. Recent research suggests
169 80 that domestic cats and dogs may increase the landscape of fear around rural homesteads,
170 80 that domestic cats and dogs may increase the landscape of fear around rural homesteads,
171 81 resulting in lower rates of rodent activity and food intake (Mahlaba *et al.*, 2017). This indirect
172 81 resulting in lower rates of rodent activity and food intake (Mahlaba *et al.*, 2017). This indirect

178
179
180 82 mechanism, affecting rodent behaviour, could work synergistically with direct control
181
182 83 mechanisms such as predation of rodents by domestic carnivores, which could reduce rodent
183
184 84 density (Krijger *et al.*, 2017). Little attention, however, has been given to the potential services
185
186 85 or disservices of wild terrestrial carnivores in terms of rodent pest control.
187
188 86

189
190 87 Thus, the first objective of our study was to understand which small- and medium-sized
191
192 88 mammalian carnivores (< 15 kg, hereafter referred to as small carnivores) were present in and
193
194 89 around rural farming communities in the study area. Secondly, we set out to determine the
195
196 90 influence of the abundance of domestic animals (livestock and pets) on the probability of use
197
198 91 of an area by small carnivores; and also assess how the species richness of the small carnivore
199
200 92 community was influenced by land use. Thirdly, we wanted to capture the knowledge and
201
202 93 opinions of smallholder farming communities with respect to small carnivores. This will
203
204 94 provide an initial yet essential step towards understanding the potential ecosystem services
205
206 95 provided by small carnivores in rural agro-ecosystems, to help inform the development of
207
208 96 EBRM strategies with a strengthened biological control component.
209
210 97

209 98 2. Methods

211 99 2.1. Study area

213
214 100 We conducted the study at two rural sites (Ka-Ndengeza: S23.31003° E30.40981° and
215
216 101 Vyeboom: S23.15174° E30.39278°) in the Vhembe Biosphere Reserve, South Africa
217
218 102 (Appendix S1). Both sites receive an annual rainfall of 700-800 mm per year, with a hot wet
219
220 103 season from October to March and a cool dry season from May to August (Hijmans *et al.*,
221
222 104 2005). Natural vegetation is classified as Granite Lowveld and Gravelotte rocky bushveld
223
224 105 (Mucina and Rutherford, 2006). Vegetation is characterised by tall shrubs with few trees to
225
226 106 moderately dense low woodland on the deep sandy uplands dominated by *Combretum zeyheri*
227
228 107 and *C. apiculatum*. Low lying areas are characterised by dense thicket to open Savanna with
229
230 108 *Senegalia (Acacia) nigrescens*, *Dichrostachys cinerea*, and *Grewia bicolor* dominating the
231
232 109 woody layer, particularly the Granite Lowveld (Mucina and Rutherford, 2006).

Three major land-use types were identified in each of the villages. First, the settlement areas were used for residential purposes (hereafter settlements) (Odhiambo and Magandini, 2008). The majority of households had large gardens (50-80 m x 40-80 m) which were used to grow crops (maize (*Zea mays*), peanuts, beans (*Phaseolus vulgaris*), ground nuts (*Arachis hypogaea*), avocados mangoes, bananas, litchis, and oranges), and to overnight livestock (cattle, donkeys, sheep, goats, and poultry). The second land-use type identified was cropping areas (hereafter crops). Residents of both villages practiced either rotational cropping (maize, ground nuts, and beans) or intercropping (maize, beans, and pumpkins (*Cucurbita* spp.)). Land preparation was usually by manual labour, and preparation typically began in October or November, while planting commenced in early December. Harvesting of crops occurs in February until late April (crop dependant). Farmers reported yields varying between 5 to 20 bags (each bag weighing 50 kg) of maize and 3 to 10 bags of ground nuts (Swanepoel, unpublished data). Crop residues were typically used for livestock fodder. The third land-use type was the grazing areas, which comprised of short grass, shrubs and tall trees (hereafter grazing). In addition to communal grazing of livestock, these areas served for firewood collection and informal hunting. Due to poor land management practices, however, the grazing areas were typically severely overgrazed, with woody plants (mainly *Dichrostachys cinerea*) decreasing herbaceous production and replacing the grass and shrub layer, typically in low lying areas.

2.2. Potential small carnivore diversity and ecosystem services

We define predation of rodent pests and consumption of carrion as potential ecosystem services (Ćirović *et al.*, 2016) that could be provided by small carnivores. We estimated theoretical small carnivore diversity for our study sites by compiling a list of all small carnivore species potentially present at the study sites from the IUCN Red List of Threatened Species (IUCN, 2016) and from published literature (Apps, 2012; Cillié, 2013; Kingdon and Hoffman, 2012; Skinner and Chimimba, 2005; Stuart and Stuart, 2007). For each species we then extracted from the literature, data on the amount of rodents in their diets, and whether the species consumed carrion (Admasu *et al.*, 2004a, b; Apps, 2012; Camps, 2008; Cillié, 2013; Kingdon

140 and Hoffman, 2012; Skinner and Chimimba, 2005). We regarded species with diets that
141 included a minimum of 20% rodents as potential ecosystem service providers (Ćirović *et al.*,
142 2016). The home range size of the species potentially present, were used to determine the
143 average distance between camera traps.

144

2.3. Camera trapping and data preparation

146 We used camera trapping to determine both species richness and habitat use (occupancy) of
147 small carnivores. Our surveys were underpinned by an occupancy based modelling framework,
148 which guided the layout of camera traps (MacKenzie and Bailey, 2004). Each study area was
149 divided into a settlement area, cropping area and grazing area, based on recent satellite imagery
150 (Google, 2014), which was then overlaid with a regular spaced grid with a cell size of 300 x
151 300 m (9 ha). The size choice of the grid cells was guided by the median home range size of
152 small carnivores expected to inhabit the study areas (Table 1), to adhere to the independent
153 assumptions of occupancy models (Mackenzie and Royle, 2005). We deployed one camera
154 trap in each grid, which resulted in an average spacing between camera traps of 193 m (standard
155 deviation 65 m), and camera traps were operated for 10-12 days. Camera traps were set to
156 record 24 hours per day, with a 30 second delay between detections. We regarded individuals
157 of the same species photographed within a 5-minute period as the same individual, to avoid
158 pseudo-autocorrelation.

159

160 We deployed camera traps at roads, drainage lines, and well-established animal paths. We
161 placed cameras around 30 cm above the ground, and cleared vegetation in front of camera traps
162 to reduce the number of false triggers. In the settlement grid cells we deployed 27-30 infra-red
163 flash cameras (Cuddeback Ambush 1194), as these were less disruptive to the inhabitants of
164 villages than cameras using a visible light flash, while in the crops and grazing areas we
165 deployed 55-60 xenon flash cameras (Cuddeback Ambush 1170). Camera traps were deployed
166 between 2-26 June 2014 at Ka-Ndengeza and 17 June to 27 July 2014 at Vyeboom. This
167 resulted in a camera trapping effort of 810 trap days in Ka-Ndengeza and 738 trap days in
168 Vyeboom. From each camera trap we extracted detection-non-detection data for the target

169 species, and calculated the relative abundance index (RAI) (O'Brien *et al.*, 2003) of other
170 species we deemed important to the detection and occupancy of target species, such as domestic
171 cats and dogs, livestock, and humans.

172
173 To classify land use we first digitized the different land-use types using satellite imagery from
174 Google Maps (Google, 2014), which we later ground-truthed. This approach allowed us to plan
175 the locations of our camera traps for optimal spacing, stratified by land use. We classified crops
176 as either active fields, i.e. still showing agricultural activity, or as abandoned fields. For each
177 camera trap we calculated the percentage of crops, grazing and settlement that comprised the
178 camera trapping grid cell in which each camera trap was located. Camera trap images were
179 catalogued using Camera Base version 1.7 (Tobler, 2015).

180

181 2.4. Questionnaires

182 We assessed the opinions of community members towards small carnivores using a structured
183 questionnaire (Appendix S2) (based on the questionnaire used by Holmern and Røskaft
184 (2014)), completed by a total of 127 respondents (n = 58 in Ka-Ndengeza and n = 69 in
185 Vyeboom). For each camera trap the inhabitants of the nearest household were sampled, but
186 when this was not possible another nearby house was selected. Photographs of small carnivore
187 species were provided to ensure that the species were correctly identified. We asked
188 interviewees whether they had seen each species of carnivore, if they were good for the
189 community, if they kill rodents, if they had impacted the respondents negatively, and if they
190 were aware if any small carnivore species that are killed by people. The reasons for any positive
191 and negative impacts of the species were also recorded. We also asked whether interviewees
192 consider poultry to be an important source of protein, in order to gain some insight into the
193 motivations for farming chickens and protecting them by killing carnivores.

194
195 Ethical approval for the study was provided by the Ethics Committee of the University of
196 Venda (approval number SMNS/14/ZOO/03/2803). We also obtained consent to interview

198 to community members. We informed each respondent that anonymity would be maintained,
199 and obtained written consent from interviewees.

2.5. Data analysis

2.5.1. Community occupancy (probability of use) model

203 We used the MaoTau function in the EstimateS package (Colwell, 2016) to generate species
204 accumulation curves to confirm sampling adequacy for the camera trap dataset (Gotelli and
205 Colwell, 2011). We also used the camera trap data to estimate how the relative abundance of
206 domestic animals influenced small carnivore occupancy, which can be defined as the
207 proportion of the study site that was occupied by the study species (MacKenzie *et al.*, 2017).
208 This is of interest because domestic animals could outcompete sympatric wild carnivores
209 (Vanak and Gompper, 2009), reducing their capacity to provide ecosystem services. Due to the
210 fact that little is known regarding home range and movement rates of South African small
211 carnivores (Roemer *et al.*, 2009), we considered among-grid cell movement in small carnivore
212 species a plausible violation of the closure assumption. As such the occupancy parameter (ψ)
213 should be considered to represent the proportion of area used rather than the proportion of area
214 occupied (MacKenzie and Bailey, 2004).

215
216 We adopted the hierarchical formulation of the Dorazio/Royle community occupancy model
217 with data augmentation to estimate species-specific occupancy and site-specific species
218 richness (Dorazio and Andrew Royle, 2005). In a single-species single-season occupancy
219 model the probability that site j is occupied by species z_j is a Bernoulli random variable
220 governed by the occupancy probability Ψ . The occupancy probability is modelled on the logit
221 scale as either a function of site specific covariates or being constant. Analogous to occupancy,
222 the probability that a species is detected is governed by the detection probability, p , which is
223 conditioned on the true latent occupancy state, z_j . Survey sites are camera trapped on k
224 occasions (e.g. days) where the observations, y_{jk} , is a Bernoulli random variable, either $p_{jk} = 1$

473
474
475 225 where $z_j = 1$ or $p_{jk} = 0$ where $z_j = 0$. Detection probability is also modelled on the logit scale,
476
477 226 either constant or as a function of site (e.g. vegetation type) or occasion (e.g. daily temperature)
478
479 227 specific covariates.
480

481 228

482
483 229 We fitted community models to the data, as this allowed us to investigate the influence of the
484
485 230 relative abundance of domestic animals on small carnivores at a community level (MacKenzie
486
487 231 *et al.*, 2017). In the community model formulation the single-species single-season model is
488
489 232 further extended where the latent and model parameters are indexed by species, i . This
490
491 233 formulation results in a number of linked species-specific models because it is assumed that
492
493 234 these species-specific parameters come from a common underlying distribution (governed by
494
495 235 the hyperparameters, which in our study is the small carnivore community). To estimate the
496
497 236 number species at each sampling site (including ones never detected) we augmented the data
498
499 237 with all-zero observations for the hypothetical species (Dorazio and Andrew Royle, 2005). We
500
501 238 hypothesized that in our study area a potential 23 small carnivore species could occur (IUCN,
502
503 239 2016), and we therefore augmented the observed data with 14 species.
504

505 240

506 241 We expected occupancy and diversity of small carnivores to be affected by various
507
508 242 anthropogenic and environmental variables. To investigate these variables we developed an *a*
509
510 243 *priori* model based on biological hypotheses on how small carnivore occupancy could be
511
512 244 influenced by these variables. We hypothesized that small carnivore occupancy will be affected
513
514 245 by the presence of domestic cat, dogs, livestock, humans and land use. Both domestic cats and
515
516 246 dogs can either directly (through predation) or indirectly (through competitive exclusion)
517
518 247 impact small carnivores (Brook *et al.*, 2012; Dickman, 1996). Similarly, humans can directly
519
520 248 kill small carnivores (Berger, 2006; Ćirović *et al.*, 2016), and livestock can trample burrows of
521
522 249 small carnivores and reduce vegetation cover (Blaum *et al.*, 2007a; Blaum *et al.*, 2007b). We
523
524 250 used variance inflation factor (Zuur *et al.*, 2009) to identify and remove highly correlated
525
526 251 variables to reduce multicollinearity. Using all the covariates we sequentially dropped the
527
528 252 variable with highest VIF (however, we selected the variable with the least biological effect
529
530 253 among variables with high VIF first), and recalculated the VIF until the VIF of each factor was

254 below five (Zuur *et al.*, 2009). Using this approach we dropped percentage crops, settlement
255 and grazing as these variables were highly correlated and had high VIF factors. Both human
256 RAI and dog RAI were correlated and we thus dropped human RAI since we hypothesised that
257 domestic dogs can have higher sustained impact on small carnivores (e.g. since dogs can roam
258 over the landscape independent of humans).

259
260 We thus retained only domestic cat RAI, domestic dog RAI, and livestock RAI as explanatory
261 occupancy covariates, and we modelled occupancy probability as having species-specific
262 random intercepts with these three site covariates. We assumed that occupancy patterns were
263 similar across villages, even though they were not sampled at the same time. For detection
264 probability we only modelled the effect of survey date (Julian day) on detection, again as
265 species-specific random intercept (Dorazio and Andrew Royle, 2005). We collapsed the 10-12
266 day survey into 5 sampling occasions to increase detection probabilities (Ramesh *et al.*, 2012),
267 and each camera trap was regarded as independent.

268
269 We used a Bayesian framework (Plummer, 2003) to implement the community model. Full
270 details can be found in Appendix S3, while the full model specification can be found in
271 Appendix S4. Results are reported in mean, standard deviation and 95% Bayesian confidence
272 intervals (95 BCI taken from the 2.5% and 97.5% percentiles of the posterior mean). We
273 regarded coefficients as having strong inference value if its 95 BCI values did not include 0.
274 We further estimated the number of small carnivore species per land use by summing the
275 estimated species richness at each survey site, in each land use. Finally we used the estimated
276 species richness at each camera trap location to create spatially explicit species richness maps
277 using inverse distance weighted interpolation (Sarmiento *et al.*, 2010). We used R v3.4.1 (R
278 Development Core Team, 2017) for all modelling, with the following R packages; raster for
279 IWD (Hijmans, 2015), jagsUI (Kellner, 2016).

281 2.5.2. Questionnaires

282 The questionnaire data allowed us to investigate stakeholder perceptions of small carnivores in
283 agro-ecosystems. We explored the questionnaire data by calculating the frequency with which
284 respondents reported that 1) they had seen small carnivores; 2) small carnivores had either
285 positive or negative impacts on people; 3) small carnivores kill rodents; and 4) people kill small
286 carnivores. Some frequencies were represented graphically using bar plots created using the R
287 package ggplot2 (Wickham, 2016). All data analysed in this study are publically available in
288 Williams *et al.* (2017).

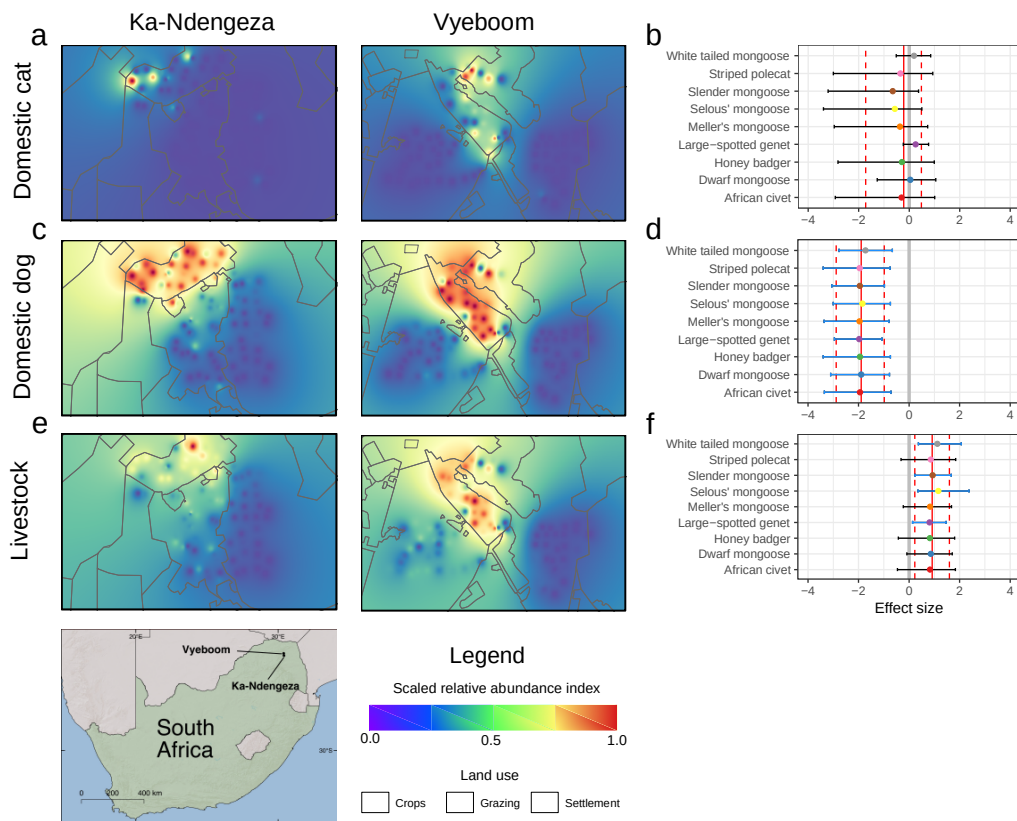

290 3. Results

291 3.1. Small and medium carnivore diversity and occupancy (probability of use)

292 Species accumulation curves plateaued at approximately 1,368 camera trapping days (8 survey
293 days), which suggested adequate sampling (Appendix S5). Of 23 small and medium carnivore
294 species potentially occurring at the study sites (IUCN, 2016), we detected 9 (8 at Ka-Ndengeza
295 and 8 at Vyeboom) small carnivores representing 5 different families (Table 1). The mean
296 metacommunity richness was estimated at 14.48 (95 BCI 9-22 species). However the mean
297 metacommunity richness had a skewed posterior distribution and a wide credible interval. We
298 therefore used the mode to estimate total metacommunity richness, which was estimated at
299 10.98 species.

300
301 The strength of associations with occupancy covariates varied between species (Fig. 1). The
302 presence of cats did not have a strong association with any of the small and medium carnivore
303 species, nor to the metacommunity as a whole (Fig. 1). In contrast, dogs had a strong negative
304 association with occupancy probability (probability of use) for all species and the
305 metacommunity (Fig. 1). For livestock only four species (white tailed mongoose, slender
306 mongoose, Selous' mongoose, and large spotted genet) showed strong positive associations
307 with livestock presence, while the other five species had no association. Interestingly, the

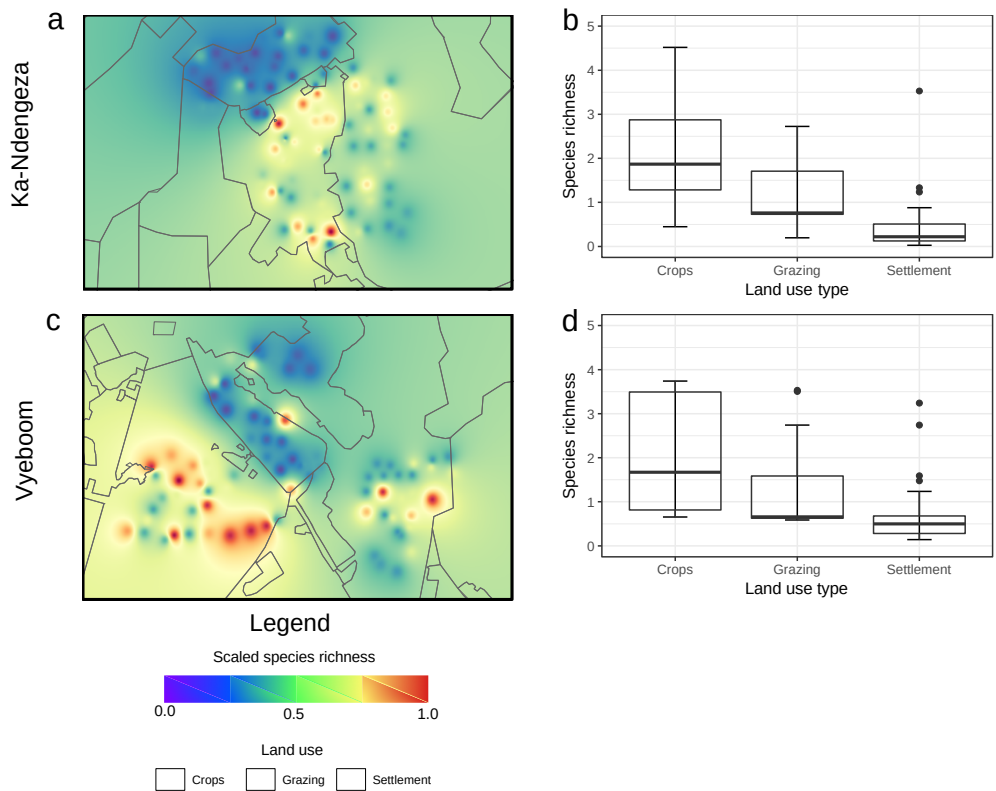

650
651
652 308 metacommunity also had a strong positive association with livestock presence (Fig. 1).

685 313 in Ka-Ndengeza and Vyeboom. Caterpillar plots show the strength of associations between the
686 314 RAI of b) domestic cat, d) domestic dog, and f) livestock with occupancy (probability of use)
687 315 of the nine carnivore species detected. Confidence intervals highlighted in blue do not overlap
688 316 0. The broken lines indicate the 95 BCI for the mean community response to each variable.
689
690
691
692

693 317
694
695 318 Cropping areas consistently showed higher species richness than grazing and settlement areas
696 319 (Fig. 2). Spatially, species richness density surfaces clearly adhered to cropping areas and
697 320 highest species richness per 900 m² grid cell were consistently observed in the cropping areas
698 321 (Fig. 2). A survey of the literature showed that 65% of these species (15/23) are reported to

707
708

709
 710
 711 322 have at least 20% of rodents in their diet (Table 1). Combined with species richness maps this
 712
 713 323 suggests that the small and carnivore community not only occur most often in cropping areas,
 714
 715 324 but also probably incorporate a large proportion of rodents in their diet. Using the mode small
 716
 717 325 carnivore richness (10.98) as a reliable estimate of species richness we suggest that the study
 718
 719 326 area realised around 47% of the potential small carnivore diversity.

352

950
951
952 353 A total of eight species of non-domesticated carnivores were believed by some people to kill
953
954 354 rodents (Ka-Ndengeza: seven species were thought to kill rodents by a mean of 17.5% of
955
956 355 respondents; Vyeboom: six species were thought to kill rodents by a mean of 23.0% of
957
958 356 respondents). The species most commonly thought to predate on rodents were African wildcat,
959
960 357 striped polecat, and slender mongoose (Table 2).

961 358

962
963 359 Negative impacts of carnivores on people were reported for most mongoose species, black
964
965 360 backed jackal, small spotted genet, and African wild cat (Table 2). Most negative impacts were
966
967 361 perceived to be due to poultry predation, although a small number of respondents cited cultural
968
969 362 reasons, such as involvement in witchcraft or other superstitions, for negative impacts
970
971 363 (Appendix S7).

972 364

973
974 365 Slender mongoose, dwarf mongoose, yellow mongoose, and African wildcat were said to be
975
976 366 killed by people (Table 2). The only reason provided for people killing carnivores was poultry
977
978 367 predation. Poultry was considered to be an important source of protein by 98.3% of respondents
979
980 368 in Ka-Ndengeza and 100.0% of respondents in Vyeboom. The median number of chickens
981
982 369 owned was 10 (interquartile range = 13, n = 21) in Ka-Ndengeza, and 4 (interquartile range =
983
984 370 6, n = 24) in Vyeboom. Poultry were almost always free-ranging (in 96.6% and 100% of
985
986 371 households surveyed in Ka-Ndengeza and Vyeboom respectively).

987 372

988 373 4. Discussion

989
990
991 374 Our camera trapping results indicated that cropping areas consistently supported the greatest
992
993 375 diversity of small carnivores. Furthermore, the literature review showed that the small
994
995 376 carnivore assemblages present typically incorporate a large percentage of rodents and carrion
996
997 377 in their diets. Collectively these results highlight the potential for pest control and carrion
998
999 378 removal by small carnivores as important ecosystem services. Our results concur with other
1000
1001 379 studies that highlight the unrealised potential of small carnivore predation and scavenging as
1002
1003 380 ecosystem services (Ćirović *et al.*, 2016; Mateo-Tomás *et al.*, 2015). Rodent pests, for example,

1009
1010
1011 381 account for approximately 15% of the damage caused to rural farming crops in Africa
1012
1013 382 (Swanepoel *et al.*, 2017), and such damage is dependent on the density of rodents (Brown *et*
1014
1015 383 *al.*, 2007). Since small carnivore diets include a large proportion of rodents, it is likely that
1016 384 small carnivore predation could be a key factor affecting rodent abundance, and therefore
1017
1018 385 reduce crop damage (Ćirović *et al.*, 2016). Further support comes from meta-analysis studies,
1019 386 that show that reduced predation increases population growth for cyclic prey (Salo *et al.*, 2010)
1020 387 and provisioned populations of small mammals such as rodents feeding on grain (Prevedello
1021 388 *et al.*, 2013; Salo *et al.*, 2010). There therefore appears to be strong support, both from our
1022
1023 389 findings and from the literature, that predation of rodents by small carnivores could be an
1024
1025 390 important ecosystem service to rural communities through EBRM.
1026
1027

1028 391
1029
1030 392 Our results showed that abundance of domestic dogs (and feral dogs) and livestock are
1031 393 important determinants of small carnivore diversity and habitat use, while cats seemed to have
1032
1033 394 little effect. Several studies have highlighted the negative impact of dogs (domestic and feral)
1034 395 on native mammalian communities (Hughes and Macdonald, 2013; Reed and Merenlender,
1035 396 2011). For example, dogs can act as intraguild competitors where they can outcompete
1036
1037 397 carnivores, especially under conditions of low prey biomass (Vanak and Gompper, 2009). We
1038 398 suggest that such a scenario is most likely prevalent in rural African landscapes where local
1039
1040 399 fauna often form part of the diet of people in rural areas (Holmern *et al.*, 2006). Furthermore
1041 400 dogs, especially when roaming freely (a scenario common in African rural landscapes
1042 401 (Czupryna *et al.*, 2016)), can kill small carnivores (Ralls and White, 1995). Finally, dogs are
1043 402 often used during hunting activities where they can kill non-target species such as small
1044
1045 403 carnivores (Holmern *et al.*, 2006).
1046
1047
1048
1049

1050 404
1051
1052 405 The lack of effect of cats on small carnivore occupancy is surprising, given the large impact
1053 406 cats have on mammalian communities (Loss *et al.*, 2013). We provide two possible reasons for
1054
1055 407 this lack of effect; first cats most often include small mammals in their diet (Loss *et al.*, 2013),
1056 408 and as such might impact small carnivores through competitive exclusion (Brook *et al.*, 2012).
1057
1058 409 However, densities of cats in our study might not be high enough to achieve such an effect.
1059
1060
1061

1068
1069
1070 410 Secondly, dog hunting often occurs at night (Holmern *et al.*, 2006), which might restrict cats
1071
1072 411 (and hence their impact on small carnivores) to the settlement areas. The positive effect of
1073
1074 412 livestock contrasts with other studies that highlight the negative impact of livestock on small
1075 413 carnivores (Blaum *et al.*, 2007a; Blaum *et al.*, 2007b). We hypothesised that this effect is
1076
1077 414 probably mediated through invertebrate food sources for small carnivores. For example the
1078 415 four small carnivore species exhibiting a positive occupancy effect due to livestock (large
1079
1080 416 spotted genet, slender mongoose, white tailed mongoose and Selous' mongoose) all
1081
1082 417 incorporate a large proportion of invertebrates in their diet (Skinner and Chimimba, 2005).
1083 418 Studies have shown that disturbance-adapted insect populations increase in abundance in
1084
1085 419 highly impacted areas (e.g. heavy grazed) (Schowalter, 1985; Seymour and Dean, 1999).
1086 420 Therefore, the presence of livestock can create local conditions of increased invertebrate
1087
1088 421 biomass, which could facilitate small carnivore presence.

1089
1090 422
1091
1092
1093 423 We found that cropping areas had the highest small carnivore richness, which contrasts with
1094 424 the low biodiversity often observed in intensive agricultural systems (Benton *et al.*, 2003). We
1095
1096 425 provide several hypotheses for this observation, which are not necessarily mutually exclusive.
1097 426 First, rural agricultural landscapes are often structurally complex and heterogeneous (Donald,
1098
1099 427 2004) which seems to support higher animal diversity (Norris, 2008). Secondly, rural
1100
1101 428 agricultural systems support a diverse and high rodent abundance, especially in our study areas
1102 429 (Belmain, 2006), which can support small carnivores (Blaum *et al.*, 2007b). While dogs had a
1103
1104 430 large effect on small carnivores, the highest dog and cat activities were observed in the
1105
1106 431 settlement areas, and to a lesser extent in the cropping areas, which suggests that competitive
1107 432 exclusion and competition with small carnivores (Glen and Dickman, 2005; Vanak and
1108
1109 433 Gompper, 2010) is limited in agricultural areas. Finally livestock abundance was higher in
1110
1111 434 cropping areas compared to grazing areas, which could have created favourable conditions for
1112 435 high biomass of disturbance-adapted insect populations that can act food resource for small
1113
1114 436 carnivores (Seymour and Dean, 1999).

1115
1116 437
1117
1118 438 While our results support the hypothesis that small carnivores could provide ecosystem

1127
1128
1129 439 services, we highlight that such a service would not depend solely on diversity, but also
1130
1131 440 abundance of small carnivores. Our results show that the majority of small carnivores had low
1132
1133 441 relative abundance indices, which were likely to be below ecologically effective densities
1134
1135 442 (Soulé *et al.*, 2005). Nonetheless, the small carnivore assemblage present in these rural agro-
1136
1137 443 ecosystems can still fulfil basic ecological functionality of predation (Roemer *et al.*, 2009).
1138
1139 444 Such functionality will be largely dependent on whether the small carnivore assemblages
1140
1141 445 retained inherent functional redundancy (Roemer *et al.*, 2009; Suraci *et al.*, 2017). This is
1142
1143 446 important since the ecosystem service provision can be greater if expressed through collective
1144
1145 447 effects, where the sum effect of predation (from different carnivores) might exceed that of a
1146
1147 448 single small carnivore (Suraci *et al.*, 2017). Our study shows that the system retained some
1148
1149 449 functional redundancy, however a large number of rodent specialists (e.g. striped polecat) were
1150
1151 450 not detected or occurred at low relative abundances. Their absence probably reflects the small
1152
1153 451 carnivore assemblage responding to pressures and changes as a result of human modification
1154
1155 452 to the landscape that exist around rural agro-ecosystems. These responses will inadvertently
1156
1157 453 bring shifts and changes in ecosystem service delivery and provision, which, if not checked
1158
1159 454 can ultimately only exist as simple linear food chain communities (Roemer *et al.*, 2009).
1160
1161 455 Therefore facilitating or at least maintaining small carnivore functional redundancy should be
1162
1163 456 a key conservation management action in rural African landscapes if ecosystem services are to
1164
1165 457 be maintained. Changes in rural landscapes are dynamic, which could potentially allow for
1166
1167 458 various species of small carnivores to persist in them (Melo *et al.*, 2013). However, to what
1168
1169 459 extent these changes retain or enhance functional redundancy remains to be explored.

1164 460

1166 461 Encouragingly, community members were able to identify 11 native small carnivore species
1167
1168 462 that should occur in their areas, although we recorded fewer species using camera traps (nine
1169
1170 463 wild species, domestic cats and domestic dogs). Although respondents were aware of the
1171
1172 464 presence of the study species in their villages, and many respondents acknowledged the
1173
1174 465 presence of rodents in the diet of some wild small carnivore species, they lacked any
1175
1176 466 appreciation of the ecosystem services that they could provide. Reports of negative impacts of
1177
1178 467 small carnivores were commonplace, almost exclusively due to perceived poultry predation. In
1179
1180 468 both villages keeping of poultry was very common, and almost all respondents asserted that

1186
1187
1188 469 poultry was an important source of protein in their diet. The threat of poultry predation was
1189
1190 470 said to be the main motivation for small carnivores being killed by community members.
1191

1192 471
1193
1194
1195 472 The mechanism by which some small carnivores were thought to predate on poultry was
1196 473 unconventional and unsubstantiated. Many community members believed that carnivores
1197 474 would intentionally trap the beaks of chickens in their anus, before breaking their necks.
1199 475 Although some species of small carnivores such as the African civet, small spotted genet, and
1200 476 large spotted genet have been known to predate on poultry (Kingdon and Hoffman, 2012), and
1202 477 in some cases levels of poultry predation by small carnivores can be high (Holmern and
1203 478 Røskaft, 2014), such perceptions illustrate that the perceived threats of predation may not
1205 479 always have a strong grounding in reality. Nevertheless, it appears that overcoming perceptions
1207 480 of poultry predation will be the key challenge in promoting the role of small carnivores as
1208 481 providers of ecosystem services. Our results could help to demonstrate to community members
1210 482 that wild small carnivores are more likely benefit them by controlling pests and removing
1211 483 carcasses than predate on their poultry. We note that the wording of the questionnaires
1212 484 (Holmern and Røskaft, 2014) could be improved upon to reduce bias. As an example, we
1215 485 suggest that in future studies asking respondents to rate their benefit of a carnivore species on
1216 486 a Likert scale would be less biased than asking if a species is good for the community (Morgan-
1218 487 Brown *et al.*, 2010).
1219
1220

1221 488
1222
1223 489 Although our findings indicate that small carnivores could provide ecosystem services through
1224 490 pest control and waste removal in rural agro-ecosystems, we suggest that further research may
1225 491 help to characterise the impacts of small carnivores on the density and diversity of rodents in
1226 492 agricultural fields, the amount of crop damage caused by rodents, and the amount of carrion
1229 493 removed. The socio-economic implications on the livelihoods of people adopting these
1230 494 strategies would also be worthy of further study.
1231

497 Our findings suggest that agricultural areas could be important refuges for small carnivores
498 within modified landscapes, and these species are likely to be providing important ecosystem
499 services in rural agro-ecosystems. We found that agricultural areas supported the the greatest
500 diversity of small carnivores. Livestock was linked to higher levels of occupancy (probability
501 of use) of small carnivores, while the opposite trend was observed for domestic dogs, and
502 domestic cats had no influence on carnivore occupancy. The small carnivore species present
503 are reported in the literature to dedicate a considerable proportion of their diets to rodents, and
504 consume carrion. Although community members could identify many small carnivore species,
505 they appeared to be unaware of the ecosystem services that the small carnivores are likely to
506 provide through EBRM and carcass removal. The perceived threat of poultry predation
507 emerged as a key challenge in promoting the role of small carnivores as providers of ecosystem
508 services.

510 6. Appendices

- 511 Appendix S1. Study area figure
- 512 Appendix S2. Interview schedule.
- 513 Appendix S3. Model description and parameter estimates of the community occupancy model
514 applied to small carnivore camera trapping data from a rural matrix.
- 515 Appendix S4. Community model JAGS code used in the analysis.
- 516 Appendix S5. Species accumulation curves to show sampling adequacy.
- 517 Appendix S6. Percentage of respondents in Ka-Ndengeza and Vyeboom that reported seeing
518 species of small carnivores.
- 519 Appendix S7. Reasons provided why carnivores have impacted respondents negatively for Ka-
520 Ndengeza and Vyeboom.

11) Do you own:

12) How many?

13) Do you feed them?

- Cat Yes/No/Communally owned Male:..... Female:..... Yes/No Daily/Weekly/>
- Dog Yes/No/Communally owned Male:..... Female:..... Yes/No Daily/Weekly/>

13) You don't have a rodent problem because you have cats? Yes/No/UN

14) Does cats bring stuff to house? Yes/No 15) What? Birds / Reptiles / Rodents / Other

16) Do you own livestock?

17) Do you own poultry?

18) Are poultry free ranging?

- Cattle Nr..... Chickens Nr..... Yes
- Pigs Nr..... Geese Nr..... No
- Sheep/goats..... Other Nr..... Where do they sleep.....

19) Are poultry and important protein source? Yes/No

Williams et al. Predation by small mammalian carnivores in rural agro-ecosystems: An undervalued ecosystem service?

Appendix S3. Data summary and formal model description for the multispecies occupancy model applied to small carnivore data obtained from camera traps in a rural agricultural matrix, Vhembe District, South Africa.

Camera trapping was done in two villages, Vyeboom and Ka-Ndengeza, in the Vhembe District of South Africa. Villages were close to one another and we analyzed data as a single dataset. We used a Dorazio/Royle (DC) community occupancy model with data augmentation (DA) (Dorazio and Royle 2005) to analyse camera trapping data obtained from sampling the two villages, where we detected 9 small carnivore species and augmented the data with 13 potential species occurring in area (Table 1; Main Text). We specifically aimed to spatially estimate small carnivore species richness over the different land uses in order to investigate potential ecosystem services that can be derived from small carnivore predation on pests. We followed a species specific parameterisation with random effects on detection and occupancy (e.g. species specific relationships with covariates).

The community occupancy model was parameterized as follows:

$$w_k \sim \text{Bernoulli}(\Omega) \text{ \# Superpopulation process}$$

$$z_{ik} | w_k \sim \text{Bernoulli}(w_k \psi_k) \text{ \# State process (occurrence)}$$

$$y_{ijk} | z_{ik} \sim \text{Bernoulli}(z_{ik} p_{ijk}) \text{ \# Observation process (detection)}$$

$$\text{\# models of species heterogeneity (Eq. S1) } \text{logit}(\psi_{ik}) = \text{lp}_k + \beta 1_k \text{Cat}_i + \beta 2_k \text{Dog}_i + \beta 3_k \text{Livestock}_i$$

$$\text{\# (Eq. S2) } \text{logit}(p_{ijk}) = \text{lp}_k + \beta \cdot \text{Date}_{ij}$$

with

$$lpsi_k \sim Normal(\mu_{lpsi}, \sigma_{lpsi}^2)$$

$$\beta1_i \sim Normal(\mu_{\beta1}, \sigma_{\beta1}^2)$$

$$\beta2_i \sim Normal(\mu_{\beta2}, \sigma_{\beta2}^2)$$

$$\beta3_i \sim Normal(\mu_{\beta3}, \sigma_{\beta3}^2)$$

$$lp_k \sim Normal(\mu_{lp}, \sigma_{lp}^2)$$

$$\beta.d1_i \sim Normal(\mu_{\beta.d}, \sigma_{\beta.d}^2)$$

In this model parameterization we augmented the observed species with species never detected (but that we hypothesised could occur in the study area), which is represented by a Bernoulli random variable (w), which indicates that the species is part of the metacommunity studied (e.g. data augmentation variable; (Kéry and Royle 2015)). z_{ik} represents the true occupancy state where 0 indicates not occupied and 1 occupied for a species k at site i ; ψ_{ik} represents the occupancy probability (between 0 and 1) for each species k ; $lpsi_k$ is the logit-linear predictor intercept of occupancy probability, which is indexed by species (k). $\beta1$ is the coefficient for the Relative abundance of cats (expressed as number of pictures/1000 camera trapping days), $\beta2$ the coefficient for relative abundance of dogs and $\beta3$ coefficient for relative abundance of livestock. Species specific intercepts and coefficients comes from Normal distributions with mean (μ_{lpsi}), and variance (σ_{lpsi}^2) for the community, mean ($\mu\beta1 - \mu\beta3$) and variance ($\sigma^2\beta1 - \sigma^2\beta3$) for coefficients. Similarly, y_{ik} are the species detections (1 being detected and 0 not detected) of k species at i sites; p_{ik} is the detection probabilities per species, lp_k is the logit-linear predictor intercept of detection probability, which is again indexed by species (k). $\beta.d$ is the effect of Julian survey date on detection probability. The species specific detection intercepts were drawn from a Normal distribution with community mean (μ_{lp}) and variance (σ_{lp}^2) and for Julian date coefficient mean ($\mu\beta.d$) and variance ($\sigma^2\beta.d$).

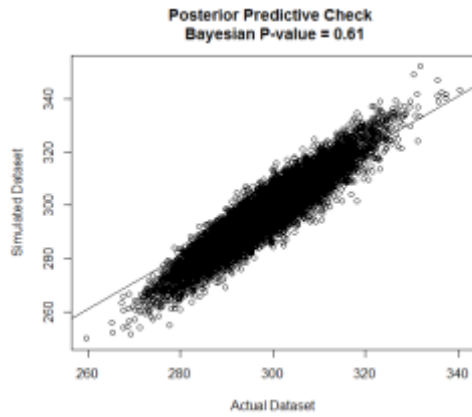

We used a Bayesian framework to implement the community occupancy model using JAGS (Plummer 2003) ported through R (RDevelopmentCoreTeam 2012) using the R package ‘jagsUI’ version 1.4.4 (Kellner 2015). We ran three parallel Markov chains with 50 000 iterations, where we disregarded 10 000 as burn-in and thinned the remaining chains by 10. We assessed chain convergence first by visually inspecting chains and calculating the Gelman-Rubin statistic (Gelman et al. 2014), where values of <1.1 indicated convergence. In our analysis all parameters had R values <1.1 which adequate chain mixing and convergence. We tested model fit by calculating the Bayesian p -value (Gelman et al. 1996) by comparing the observed residuals to residuals simulated under the model. Under perfect model fit we would expect the Bayesian p -value to be around 0.5, while values >0.95 indicate lack of fit.

We used the Freeman-Tukey residuals, R , in the calculation of the Bayesian p -value, where

$$R(\mathbf{y}, \boldsymbol{\theta}) = \sum (\sqrt{y} - \sqrt{E(y)})^2.$$

In this equation, \mathbf{y} represent the binary observations, $\boldsymbol{\theta}$ represents all parameters in the community occupancy model. $E(y)$ is the expected value of y , which is the product of the species, site and the species specific detection and occupancy probabilities. The residuals are then summed over species, sites and occasions (see code for full parameterizing).

Our model simulations resulted in a Bayesian p -value of 0.61 which indicated a good fit of our community occupancy model.

We present model parameter estimates only for the 9 detected species; for the augmented species model parameters are equivalent to the hyperparameter estimates. We report on the following parameters: (Table S3-1) is the community level parameters, (Table S3-2) species-specific estimates of the occupancy intercept ψ , (Table S3-3) species specific estimates of β_{cat} , (Table S3-4) species specific estimates of β_{dog} , (Table S3-5) species specific estimates of $\beta_{livestock}$, (Table S3-6) species-specific estimates of the intercept for the logit-linear predictor of detection probability, (Table S3-7) and estimates of species-specific effect of Julian date on detection (on logit scale).

Table S3-1: Hyperparameter posterior summaries (metacommunity estimates) for a community occupancy model fitted to data obtained from camera traps in a rural agricultural matrix, Vhembe District, South Africa, during 2014. Mean and SE = posterior mean and standard deviation; 2.5%, 50% and 97.5% = respective percentiles of the posterior.

Williams et al. Predation by small mammalian carnivores in rural agro-ecosystems: An undervalued ecosystem service?

Appendix S4. Jags code for the multispecies occupancy model applied to small carnivore data obtained from camera traps in a rural agricultural matrix, Vhembe District, South Africa.

```
model {
