31

32 **Summary**

33

34 Bees visit flowers to collect nectar and pollen that contain nutrients and simultaneously
35 facilitate plant sexual reproduction. Paradoxically, nectar produced to attract pollinators
36 often contains deterrent or toxic plant compounds associated with herbivore defence. The
37 functional significance of these nectar toxins is not fully understood, but they may have a
38 negative impact on pollinator behaviour and health, and ultimately plant pollination.

39 This study investigates whether a generalist bumblebee, *Bombus terrestris*, can detect
40 naturally occurring concentrations of nectar toxins. Using paired-choice experiments, we
41 identified deterrence thresholds for five compounds found in the nectar of bee-pollinated
42 plants: quinine, caffeine, nicotine, amygdalin, and grayanotoxin. The deterrence threshold
43 was determined when bumblebees significantly preferred a sucrose solution over a sucrose
44 solution containing the compound. Bumblebees had the lowest deterrence threshold for the
45 alkaloid quinine (0.01 mM); all other compounds had higher deterrence thresholds, above the
46 natural concentration range in floral nectar. Our data combined with previous work using
47 honeybees suggest that generalist bee species have poor acuity for the detection of nectar
48 toxins. The fact that bees do not avoid nectar relevant concentrations of these compounds is
49 likely to indicate that it is difficult for them to learn to associate floral traits with the presence
50 of toxins, thus, maintaining this trait in plant populations.

51

52 Key words: Pollinator, *Bombus terrestris*, nectar toxin, grayanotoxin, behaviour, deterrence
53 threshold

54

55 **Introduction**

56

57 Pollination is a key ecosystem service provided by flower-visiting animals. It is estimated
58 that the fitness of over 87% of the world's angiosperm species are animal pollinated and thus
59 potentially influenced by pollinator foraging behaviour (Ollerton et al., 2011) because patterns of
60 floral visitation by nectar- and pollen-collecting animals influence the quantity and quality of
61 pollination events (Aizen and Lawrence, 2007). In order to attract vital pollinators many
62 plants produce sugar-rich nectar, the primary function of which is to reward animals for
63 visiting flowers (Heil, 2011). Nectar is the principle source of carbohydrates for most flower-
64 visiting insects (Michener, 1974; Nicolson, 2011), however this reward can paradoxically
65 contain low concentrations of potentially deterrent or toxic plant compounds. These
66 secondary compounds, such as alkaloids, phenolics, and non-protein amino acids, are
67 produced in plant tissues as a means of chemical defence against herbivores (Adler, 2000;
68 Baker and Baker, 1975; Baker, 1977). Expression of toxins in nectar can be affected by
69 herbivorous attack, and so the naturally occurring concentrations to which pollinators are
70 exposed can fluctuate (Adler et al., 2006). Many adaptive functions have been proposed to
71 explain the presence of these compounds in nectar, including deterring nectar robbers (Baker
72 et al., 1978; Janzen, 1977), altering pollinator behaviour (Baker and Baker, 1975; Ehlers and
73 Olesen, 1997; Rhoades and Bergdahl, 1981; Wright et al., 2013), and providing antimicrobial
74 properties that can benefit both the plant (by preserving the nectar quality for pollinators
75 (Hagler and Buchmann, 1993; Adler, 2000)) and the pollinators (by medicating against
76 harmful pathogens and parasites (Manson et al., 2010)). The functional significance of
77 toxins in nectar is likely to depend on the ecological context and the nature of the toxin, but
78 we still know relatively little about their influence on pollinators.

79

80 Understanding the significance that nectar toxins have on plant-pollinator interactions
81 requires knowledge of how pollinators alter their behaviour in response to consumption of
82 these compounds. For example, pollinators may avoid toxin-contaminated nectar: honeybees
83 reject nectar containing nicotine, and several wild bee species avoid foraging on plants
84 containing high concentrations of the alkaloid gelsemine (Adler and Irwin, 2005; Detzel and
85 Wink, 1993; Hagler and Buchmann, 1993). Occasionally the opposite has been
86 demonstrated: for example, free flying honeybees prefer solutions containing low
87 concentrations of the alkaloid caffeine, and were even found to increase visitation rates
88 (Hagler and Buchmann, 1993) or learn floral traits faster when it was present (Wright et al.,

89 2013). Most plant secondary compounds are toxic to animals however, (Rosenthal and
90 Berenbaum, 1992) and their ingestion could represent a significant form of physiological
91 stress that would require energy or resources to metabolise or cope with the toxin (Despres et
92 al., 2007; Schuler, 2011). If consuming such plant compounds is costly, one would predict
93 that when nectar-feeders can detect toxins, they should learn to avoid plant species offering
94 toxic nectar (Adler and Irwin, 2005; Detzel and Wink, 1993; Glendinning, 2002; Hagler and
95 Buchmann, 1993). It remains unclear however, whether or not most pollinators can detect or
96 are deterred by naturally occurring concentrations of secondary compounds in nectar. If
97 these compounds do not deter pollinators, any benefit to the plant of their presence (e.g. the
98 deterrence of nectar robbers (Janzen, 1977), or suppression of nectar quality-altering
99 microbes (Adler, 2000)) would allow the trait to be maintained in the plant population.

100

101 Bumblebees such as the widespread species *Bombus terrestris*, are ecologically and
102 economically important pollinators. They are generalists that visit many plant species
103 including those containing nectar toxins (Detzel and Wink, 1993; Kretschmar and Baumann,
104 1999; London-Shafir I., 2003; Stout et al., 2006). Several studies have shown that when
105 bumblebees and honeybees detect toxins such as the bitter-tasting alkaloid, quinine, they will
106 learn to avoid floral traits associated with the compound's presence in sucrose rewards
107 (Chittka et al., 2003; Mustard et al., 2012; Wright et al., 2010). However many of these
108 studies use concentrations of toxins several orders of magnitude beyond their concentration in
109 nectar. Whether or not bumblebees can detect the same compounds at concentrations
110 encountered in floral nectar remains unknown.

111

112 Here, we performed a series of experiments to test whether *B. terrestris* was deterred by
113 naturally occurring concentrations of nectar toxins in sucrose solutions. This study is the first
114 to determine the deterrence thresholds of nectar toxins for a *Bombus* species. We discuss the
115 resultant implications concerning bee gustatory acuity and bee health, as well as how our
116 results add to the growing body of literature concerning the functional significance of toxins
117 in nectar.

118

119 **Results**

120

121 *3.1. Bumblebees are not deterred by naturally occurring concentrations of nectar toxins*

122 Bumblebees failed to be deterred by any of the compounds tested (nicotine, amygdalin,
123 caffeine and grayanotoxin (GTX)) at naturally occurring concentrations in nectar (Fig. 1). In
124 contrast, the alkaloid quinine was readily avoided even at doses as low as 0.01 mM (Fig. 1a,
125 GLM, $\chi_3^2 = 59.2$ $p < 0.001$). The pairwise comparison illustrated that bumblebees preferred
126 the pure sucrose solution (the internal control) over a quinine concentration of 0.01 mM ($p <$
127 0.001), and continued to exhibit this preference for the two highest quinine concentrations
128 (Fig. 1a).

129

130 By contrast, bumblebees had higher deterrence thresholds for the other alkaloids. While
131 nicotine was deterrent at 0.1 mM (Fig. 1b, GLM, $\chi_3^2 = 20.2$ $p < 0.001$), in tobacco flower
132 nectar it has been found at concentrations of 0.015 mM (Tadmor-Melamed et al., 2004),
133 nearly seven times lower than the deterrence threshold of *B. terrestris*. The preference of the
134 bumblebees for the pure sucrose solution continued for the 1 mM nicotine concentration, but
135 surprisingly individuals fed the highest concentration of nicotine, 10 mM, did not show a
136 preference for either solution ($p = 0.974$). They did however consume less total food than
137 individuals fed any of the four lower concentrations (Fig. 1b, $F = 3.44$ $p = 0.010$). The
138 deterrence threshold for another nectar alkaloid, caffeine, was 10 mM and was the highest of
139 all the compounds we tested (Fig. 1d, GLM, $\chi_3^2 = 10.0$ $p < 0.01$). This value is 20x higher
140 than the highest caffeine concentration found in floral nectar, 0.5 mM, (Kretschmar and
141 Baumann, 1999) and three orders of magnitude higher than the deterrence threshold for the
142 alkaloid quinine.

143

144 The bumblebees' deterrence threshold for the cyanogenic glycoside, amygdalin, was 1 mM
145 (Fig. 1c, GLM, $\chi_3^2 = 3.8$ $p < 0.05$) - more than 60x greater than the highest concentration of
146 amygdalin found in floral nectar (0.015 mM) (London-Shafir I., 2003). Finally, bumblebees
147 could not detect GTX in any of the concentrations we tested (Fig. 1e, GLM, $\chi_3^2 = 0.604$ $p <$
148 0.739).

149

150

151

152 *3.2. Compensative feeding does not occur for all nectar toxins*

153 The total amount of food consumed (sucrose solution + sucrose solution containing toxic
154 compounds) by bumblebees differed significantly depending upon which toxin was
155 consumed (Fig. 2a, GLM, $\chi_3^2 = 70.3$, $p < 0.001$). The total consumption of individuals fed
156 solutions containing caffeine, nicotine and grayanotoxins was significantly lower than that of
157 the control bumblebees ($p < 0.001$, $p = 0.002$, and $p < 0.001$ respectively). By contrast, the
158 total consumption of bumblebees fed quinine and amygdalin did not differ from control
159 bumblebees ($p = 0.244$, $p = 0.803$ respectively). The analysis of total food consumption was
160 undertaken for the lowest concentration of toxin tested, 0.001 mM, because bumblebees
161 could not detect any of the toxins at this level. The same pattern was found, however when
162 all concentrations for which the design was fully factorial across all toxins were analyzed,
163 (0.001 mM, 0.01 mM, and 0.1 mM): bumblebees fed caffeine, nicotine, and GTX consumed
164 significantly less total food than controls (GLM, $\chi_3^2 = 30.3$ $p < 0.001$).

165
166 The toxins also had a significant effect on bumblebee mortality (GLM, $\chi_3^2 = 15.9$ $p = 0.007$).
167 Bumblebees fed amygdalin and caffeine had significantly higher mortality rates than
168 individuals fed any of the other compounds or control bumblebees (Fig. 2b, $p = 0.027$ and $p =$
169 0.045 respectively). Survival of the bees fed GTX, nicotine, or quinine did not differ from
170 the control bumblebees.

171 **Discussion**

172

173 Our experiments show that bumblebees are not deterred by a variety of naturally occurring
174 levels of nectar toxins. This finding has important implications for bumblebee health and for
175 plant-pollinator interactions among *Bombus*- pollinated plants that produce toxins in their
176 nectar, such as rhododendron (containing GTX) (Stout et al., 2006) and almond tree species
177 (containing amygdalin) (Thomson and Goodell, 2002). Because the compounds we tested
178 did not have repellent effects on bumblebees at nectar relevant concentrations, these
179 pollinators are unlikely to alter their behaviour to avoid flowers with such compounds.

180

181 *4.1 Bees have poor acuity for toxins in nectar*

182 Our data, combined with previous studies using honeybees, demonstrate that generalist bees
183 have relatively low sensitivity for plant toxins in sucrose solutions. Previous work has
184 determined honeybee deterrence thresholds for caffeine, quinine, and amygdalin. This work
185 has consistently found that honeybees do not respond to levels of these compounds less than
186 10 mM (Mustard et al., 2012; Wright et al., 2010). For caffeine, the deterrence threshold
187 concentrations for honeybees and bumblebees are similar; however, bumblebees were more
188 sensitive to amygdalin and quinine in our assays (deterrence threshold 1 mM and 0.01 mM
189 respectively). Other insect taxa have greater gustatory acuity for these compounds; fruit flies
190 for example have deterrence thresholds for caffeine and quinine that are 10-100 times lower
191 than bees (Sellier et al., 2011). Similarly, gypsy moth larvae (*Lymantria dispar* (L)) are
192 deterred by caffeine at levels 100 times lower than bees (Sheilds et al., 2008).

193

194 Generalist bee species may have poor acuity for the detection of toxins in nectar because they
195 have few gustatory receptors (Grs) that can detect these compounds. For example, the
196 honeybee genome encodes only 10 orthologous genes for g-protein coupled Grs (Robertson
197 and Wanner, 2006). This is in contrast to Dipteran species such as fruit flies and the
198 mosquito, *Anopheles gambiae*, that have many more genes for Grs (flies: 68, *A. gambiae*, 76)
199 (Dunipace et al., 2001; Hill C.A., 2002; Robertson et al., 2003; Scott K., 2001). The greater
200 relative diversity of Grs in flies and other insects probably reflects stronger selection for the
201 detection of toxins in food in these species (Robertson and Wanner, 2006).

202

203 It is possible that natural selection for the ability to detect plant toxins has not been strong
204 enough to force diversification of eusocial bee's Grs to improve gustatory acuity for these

205 chemicals. This may be a consequence of eusociality, where individual bees are the
206 consumers, but selection pressures act on the colony as the reproductive unit. In solitary
207 animals, the individual bears the fitness cost of toxin consumption. In eusocial honey and
208 bumble bees, foragers collect food for the entire colony. If a forager ate nectar contaminated
209 with toxins that it could not detect, it might die, but with little impact on the fitness of the
210 colony (though more impact on bumblebees as compared to honeybees, because of their
211 relatively small colonies (Khoury et al., 2011).) Selection for the ability to detect toxins
212 would only occur when the queen and therefore the fitness of the colony was affected by
213 toxins in nectar.

214

215 Our results indicate that out of the classes of toxic compounds tested, individuals of the
216 species *B. terrestris* are relatively good at detecting and avoiding alkaloids. Even within this
217 specific class of compounds however, the deterrence thresholds varied across four orders of
218 magnitude for different chemicals (i.e. caffeine, nicotine, quinine). Alkaloids are one of the
219 most common and chemically diverse groups of plant compounds, with more than 12,000
220 structures described (Wink, 1993). The common frequency with which alkaloids are found in
221 higher plants and their toxicity has led insects to develop the ability to detect and reject these
222 chemicals in their food. The diverse chemical structures within alkaloids, however, makes
223 some easier to detect than others.

224

225

226 *4.2 Total consumption of solutions is affected by toxins in nectar*

227 Our results indicate that when bumblebees consume low, nectar relevant doses of caffeine,
228 nicotine, and grayanotoxins, their total intake of food was depressed, regardless of if they
229 could readily distinguish the two solutions. A study on *Drosophila* found the same
230 phenomenon: flies ate less total sucrose solution when the alkaloids lobeline, nicotine, and
231 strychnine were present (Sellier et al., 2011). This reduction in intake of all solutions after
232 toxin consumption may be due to post-ingestive detection of the toxins that is modulating
233 appetite (Wright et al., 2010). In addition, in our study bumblebees fed the 10 mM nicotine
234 solution consumed equal, but very small amounts of both solutions, even though their
235 deterrence threshold was at a lower concentration (0.1 mM, Fig. 1b). Consumption of this
236 concentration of nicotine could have damaged chemosensory sensilla or gustatory receptor
237 neurons of individuals, preventing them from detecting nicotine even though they were
238 capable of doing so at lower concentrations (0.1 mM) (Sellier et al., 2011).

239

240 Bumblebee colonies must reach a minimum size in order to produce new queens and males
241 (Muller and Schmid-Hempel, 1992). If consumption of toxins in floral nectar causes appetite
242 suppression in foraging workers, colonies may not reach this critical point as early in the
243 season or at all. This could result in a decrease in queen and male production, and because
244 bumblebees have an annual life cycle could have a substantial population-level effect (Gill et
245 al., 2012; Henry et al., 2012; Whitehorn et al., 2012).

246

247

248 *4.3 Functional significance of nectar toxins*

249 Bumblebees are generalist pollinators, and based on the large percentage of plants that have
250 toxins in their nectar (Baker and Baker, 1975; Baker et al., 1978) it is likely that bumblebees
251 encounter these kinds of toxins often (Adler and Irwin, 2005; Stephenson, 1982; Stout et al.,
252 2006). It is possible that legitimate pollinators such as bumblebees have therefore selected
253 for concentrations of toxins in floral nectar that remain below their deterrence level (Wright
254 et al., 2013). For example, if a honeybee learns to associate floral traits with bad-tasting
255 nectar, it will avoid flowers with these traits (Wright et al., 2010) and will potentially
256 communicate the poor quality of the nectar to other colony members or not recruit them to
257 this food source (Tan et al., 2012). In this way, individual bees could drive natural selection
258 towards concentrations of these compounds in nectar that are below their deterrence threshold
259 (Wright et al., 2013; Wright et al., 2010).

260

261 Our data suggest that in the field, low levels of toxic compounds in nectar do not affect
262 bumblebee foraging behaviour. These findings are in contrast to similar studies investigating
263 the gustatory responses of bumblebees in response to different sugars, where nectar relevant
264 concentrations and sugar identity were shown to impact bumblebee preference (Mommaerts
265 et al., 2013). Bumblebee-pollinated plants containing toxic compounds in their nectar would
266 not suffer from reduced pollination, thus allowing this plant trait to be maintained if it
267 conferred any fitness benefit to the plant. Selection for the production of toxins in nectar is
268 likely to be the result of other factors affecting nectar secretion and production, such as nectar
269 robbery, damage from herbivores, or reduction of nectar quality due to microorganisms. For
270 example, nectar toxins could be toxic or deterrent to nectar thieves but not deter legitimate
271 pollinators; thus they act in a similarly selective manner to morphological characters such as
272 sticky peduncles or narrow corolla tubes (Janzen, 1977; Stephenson, 1982).

273

274 This is the first assay to report that the deterrence thresholds of bumblebees are well above
275 nectar relevant concentrations of toxic compounds in *Bombus*-pollinated plants. Our data are
276 also the first to provide concentrations that inhibit feeding of the bumblebee for some
277 chemicals commonly found in floral nectar, and to indicate that the acuity of this generalist
278 bumblebee for nectar toxins is poor in comparison to other insect species. This work adds to
279 the growing body of research on the functional significance of nectar toxins on plant-
280 pollinator interactions and the impacts of these chemicals on bee health.

281

282

283

284 **Materials and methods**

285

286 *2.1. Subjects*

287 *Bombus terrestris dalmaninus* (Linnaeus 1758) workers from four colonies (from Agralan
288 Ltd, © Swindon) were used for each secondary compound assay (total twelve colonies). Prior
289 to use, colonies were maintained at 25-30°C and 24 h darkness and fed *ad libitum*
290 commercial pollen and, Biogluc® (Agralan) bee food.

291

292

293 *2.2. Secondary compounds*

294 Five compounds were investigated: quinine, caffeine, nicotine, amygdalin, and grayanotoxins
295 (GTX) (see Table 1). With the exception of the compound quinine, and to large extent
296 nicotine, compounds are known to naturally occur in floral nectar of plant species foraged on
297 by bees (London-Shafir I., 2003; Raguso et al., 2003; Roubik, 2002; Singaravelan et al.,
298 2006; Stout et al., 2006; Tadmor-Melamed et al., 2004; Thomson and Goodell, 2002). All of
299 the compounds except for GTX 1 were supplied by Sigma-Aldrich (Dorset, UK). GTX (a
300 mixture of GTX 1 and 3) was isolated from flowers of *Rhododendron ponticum* L. from the
301 UK using prep-HPLC. Flowers of *R. ponticum* were harvested from the Isle of Cumrae,
302 Millport, Scotland and air dried. Dried flowers (100 g) were extracted into 1 L methanol at
303 room temperature for 24 h. The extract was evaporated to dryness and redissolved in 500 ml
304 water and partitioned with hexane (500 ml) twice. The water fraction was further partitioned
305 with 300 ml chloroform four times and the chloroform partition evaporated under reduced
306 pressure to dryness, redissolved in 10 ml methanol and filtered through a 0.45µm acrodisc. A
307 10 µl sample was diluted into 990 µL methanol and a 10 µl aliquot of this diluted sample
308 injected directly onto the LC-MS. LC-MS analysis was carried out using a Waters Alliance
309 LC solvent delivery system with a ZQ MS detector on a Phenomenex Luna C18(2) column
310 (150 X 4.0 mm i.d., 5 µm particle size) operating under gradient conditions, with A = MeOH,
311 B = H₂O, C = 1% HCO₂H in MeCN; A = 0%, B = 90% at t = 0 min; A = 90%, B = 0% at t =
312 20 min; A = 90%, B = 0% at t = 30 min; A = 0%, B = 90% at t = 31 min; column temperature
313 30°C and flow rate of 0.5 ml min⁻¹. Grayanotoxin 3 was purchased commercially (Sigma-
314 Aldrich, Dorset, UK) and used as a chromatographic standard to generate a calibration curve
315 for this compound by quantification of the [M-H+formate]⁻ molecular ion in negative mode

316 with $m/z = 415.3$ and eluting at 6.71 min. A second more abundant $[M-H]^-$ ion with m/z
317 411.1 corresponded to the molecular weight of GTX 1 and eluted at 8.1 min. Using this
318 method, the two GTXs were separated by over 1 min so they could be purified from the
319 fraction by HPLC by collecting fractions by time. HPLC was carried out using a semi-
320 preparative Phenomenex Luna C18(2) column (150 X 10.0 mm i.d., 5 μ m particle size)
321 operating under the same elution programme as described above but with an increased flow
322 of 5ml min⁻¹ on a Waters Alliance LC system and a Waters fraction collector. Aliquots of
323 100 μ L were injected directly onto the column and the eluent collected in 30 s batches and
324 each collection analysed directly by LC-MS as described above to determine the content.
325 Grayanotoxins are diterpenoids with no chromophore so they cannot be detected by their UV
326 absorbance. Isolation of 4 ml of the methanol soluble partition yielded 20 mg of the main
327 compound (1) and 1 mg GTX 3 identified earlier by comparison with an authentic standard.
328 The major compound was evaporated to dryness and subjected to Nuclear Magnetic
329 Resonance spectroscopy (NMR). NMR spectra were acquired in MeOH- d_4 at 30°C on a
330 Bruker Avance 400 MHz instrument. Standard pulse sequences and parameters were used to
331 obtain 1D ¹H and 1D ¹³C spectra. Chemical shift referencing was carried out with respect to
332 internal TMS at 0.00 ppm and verified as GTX 1 by comparison to published data (Burke and
333 Dосkotch, 1990).

334

335 Nectar was collected from *R. ponticum* on the Isle of Cumrae, Millport, Scotland. A 20 μ L
336 aliquot was diluted to 200 μ L and injected directly on the LC-MS as described above, and the
337 concentration of compounds present in samples from nectar were quantified in this nectar
338 sample against calibration curves of authentic samples for both GTX 1 isolated here and
339 commercial GTX 3.

340

341 Quinine has not been reported in floral nectar, but it is widely used in behavioural studies of
342 honey and bumblebees as an aversive stimulus (Chittka et al., 2003; Mustard et al., 2012),
343 and is known to be repellent. We used it as a positive control. The concentrations at which
344 the remaining secondary compounds occur in floral nectar has been previously determined
345 (see Table 1), except for GTX, whose nectar concentration was determined in this study.

346

347

348

349

350 *2.3. Experimental protocol*

351 We determined the deterrence threshold for each secondary compound using a paired choice
352 assay in which bumblebees were offered two sucrose solutions, one with and one without the
353 compound at a variety of concentrations. Sucrose solutions (0.5 M, within the range found in
354 the nectar of bee-pollinated flowers (Baker, 1975)) were made by mixing grade II sucrose
355 (Sigma Aldrich, Dorset, UK) with deionised water. Serial dilutions were performed to obtain
356 different concentrations of each secondary compound (range of 0.001 mM-10 mM,
357 encompassing the naturally occurring concentrations of the compounds in floral nectar
358 (Detzel and Wink, 1993; Kretschmar and Baumann, 1999; London-Shafir I., 2003; Tadmor-
359 Melamed et al., 2004; Wright et al., 2013)), depending on the toxicity and availability of each
360 compound.

361

362 Worker bumblebees from each colony were removed and placed into individual plastic
363 containers. Nest bumblebees (spending most of their time caring for brood inside the nest,
364 never foraging) were avoided by refraining from using the smallest workers (Goulson et al.,
365 (2002). Bees were chilled on ice for approximately 3 min or until movement slowed,
366 measured (body length, thorax and abdomen width) and weighed, and randomly allocated to
367 a toxin concentration. Each bee remained in separate container and was allowed to acclimate
368 for at least 1 h. Forty bumblebees, ten from each of four colonies, were allocated to each of
369 the concentrations of each compound.

370

371 Assays were conducted in 650 ml plastic containers (160x110x45 mm) with lids containing 1
372 mm diameter ventilation holes. The containers had three additional 10 mm diameter holes on
373 three of the four sides where feeding tubes could be inserted horizontally. Feeding tubes
374 were 3 ml centrifuge tubes with four 2 mm holes: bees could alight on the tubes and feed
375 from the openings. Bees were given a choice between two solutions: a 0.5 M sucrose
376 solution (internal control), and an identical 0.5 M sucrose solution containing the toxin. Bees
377 were also supplied with a third tube containing deionised water. Tubes were weighed prior to
378 being inserted into the container and the bee was left to feed for 24 h in growth cabinets at
379 28°C, 60% relative humidity, and 24 h darkness, mimicking nest conditions (Heinrich, 2004).
380 Feeding tubes were then reweighed and the amount of food consumed from each calculated.
381 Identical setups containing no bees were used daily to control for the change in tube weight
382 due to evaporation (external controls) and the consumption per bee (g) was adjusted

383 accordingly. At least eight of these control setups were run for each concentration of each
384 compound. Data from individual bumblebees were only used in the analysis if bees were still
385 alive at the end of the 24 h test period.

386

387 Forty control bumblebees were fed 0.5 M sucrose in both tubes (ten from each of four
388 colonies) for comparison to bees fed toxins.

389

390

391 2.4. Data Analysis

392 Consumption data for each of the six compounds were analysed using generalised linear
393 modelling (GLM) with repeated measures. Concentration and solution type
394 (presence/absence of the toxin) were included in the model as main effects and a significant
395 interaction between the two indicated the presence of a deterrence threshold for a given
396 compound. A least significant difference (LSD) *post hoc* comparison was used for all
397 pairwise comparisons. Total consumption (cumulative consumption by each bumblebee,
398 both the internal control and the solution containing the toxin) was compared between
399 secondary compounds using concentrations for which the design was fully factorial (the three
400 lowest concentrations tested, 0.001 mM, 0.01 mM and 0.1 mM) using GLMs. Logistic
401 regression was utilized to determine if there was a significant effect of toxin on mortality.
402 All analyses were carried out using the statistical package SPSS Statistics[®], version 20
403 (IBM).

404

405 **List of Symbols and Abbreviations**

406 GTX: grayanotoxin

407 GLM: generalised linear modelling

408 Grs: gustatory receptors

409

410 **Acknowledgements**

411 We gratefully acknowledge P. Egan for chemical analysis of *Rhododendron* nectar as well as
412 for his valuable advice. We thank D. Stabler for his input into bumblebee feeding techniques
413 and setup. We also thank the TCD School of Natural Sciences technicians, P. Stafford, A.
414 Boyce, M. Linnie, S. McNamee, P. Coughlan, and J. Stone. We thank Dr. Nigel C. Veitch at
415 Royal Botanic Gardens Kew for providing NMR data and verifying the ID of grayanotoxin.

416

417

418 **Funding**

419 This project was funded by Science Foundation Ireland [grant number 10/RFP/EOB2842 to
420 J.C.S.]; and the Irish Research Council's EMBARK Postgraduate Scholarship Scheme [grant
421 number RS/2010/2147 to E.J.T.]. Additional support was provided by the USA National
422 Science Foundation through the Graduate Research Fellowship Program [to E.J.T]; and by a
423 grant funded jointly by the Biotechnology and Biological Sciences Research Council,
424 Department for Environment Food and Rural Affairs, Natural Environment Research
425 Council, the Scottish Government and the Wellcome Trust, under the Insect Pollinators
426 Initiative [BB/I000143/1 to G.A.W.].

427

428

429 **Author Contributions**

430 E.J.T. designed and executed the experiments, analyzed the data and wrote the manuscript;
431 J.C.S. designed the experiments and wrote the manuscript; P.C.S. isolated the grayanotoxins
432 and determined their concentration in floral nectar and wrote the manuscript; G.A.W.
433 designed the experiments, analyzed the data and wrote the manuscript.

568 **Table/Figure legends**

569

570 **Table 1.** Naturally occurring concentrations of nectar toxins and documented sensitivity of
571 honeybees to these compounds

572 1 This is not a comprehensive list of plant species containing these compounds; it includes
573 only plants species used to determine the concentration of compounds in nectar/pollen in the
574 references listed. 2 The nectar of plants containing quinine in other tissues (bark, leaves,
575 roots) has not been analyzed for the presence of secondary compounds. 3 LD₅₀ results from
576 oral acute toxicity tests.

577

578 **Figure 1. Mean (\pm s.e.m.) consumption (grams), controlled for evaporation by *Bombus*
579 *terrestris* of 0.5 M sucrose solution, with (light grey bars) or without (dark grey bars)
580 one of five nectar toxins.** Where bars are missing, assays were not completed due to limited
581 availability of compounds. Asterisks indicate significant differences between consumption of
582 two solutions at a given concentration according to (LSD) *post-hoc* comparisons (* = $p <$
583 0.05, ** = $p <$ 0.01, *** = $p <$ 0.001). Black arrows represent naturally occurring
584 concentrations of the compound in floral nectar.

585

586 **Figure 2. Mean (\pm s.e.m.) a. total consumption (grams), controlled for evaporation of
587 solutions at lowest concentration (0.001 mM) for each nectar toxin, and b. mortality of
588 *Bombus terrestris* fed five different nectar toxins.** Control bumblebees were fed 0.5 M
589 sucrose in both solutions so had no exposure to any toxin. N= 40 bees/toxin/concentration.
590 Lower case letters represent significant ($p <$ 0.05) differences in total consumption between
591 compounds according to least significant difference (LSD) *post hoc* comparison.

592 **Table 1.**

Secondary compound	Compound class	Naturally occurring concentration in nectar (mM)	Plant species containing compound ¹	Deterrence threshold exhibited by honeybees (mM)	Honeybee LD ₅₀ ³
Quinine	alkaloid	Unknown ²	unknown	10 mM (in 1.0 M sucrose) (Wright et al., 2010)	LD ₅₀ =0.62 mM (Toxicity of quinidine, a stereoisomer of quinine) (Detzel and Wink, 1993)
Caffeine	alkaloid	0.003 mM-.253 mM (Wright et al., 2013)	<i>Coffea canephora</i> , <i>Coffea Arabica</i> , <i>Coffea liberica</i> , <i>Citris paradisi</i> <i>Citrus maxima</i> <i>Citrus sinensis</i> , <i>Citrus reticulate</i>	10 mM (in 1.0 M sucrose) (Mustard et al., 2012)	LD ₅₀ =102 mM (Detzel and Wink, 1993)
Nicotine	alkaloid	0-0.015 mM (0-2.5 ppm) (Detzel and Wink, 1993; Tadmor-Melamed et al., 2004)	<i>Nicotiana tabacum</i> <i>Nicotinia glauca</i>	NA	LD ₅₀ =12.3 mM (Detzel and Wink, 1993)
Amygdalin	cyanogenic glycoside	0.009-0.015 mM (4-7 ppm) (London-Shafir I., 2003)	<i>Amygdalus communis</i>	10 mM (in 1.0 M sucrose) (Wright et al., 2010)	LD ₅₀ =0.066 mM (Detzel and Wink, 1993)
Grayanotoxin I&III	diterpene	0.07 mM	<i>Rhododendron ponticum</i>	NA	NA
