1. Introduction – 11 Å tobermorite ($\text{Ca}_5(\text{Si})_6\text{O}_{16}(\text{OH})_2 \cdot 4\text{H}_2\text{O}$) and its Al-substituted counterpart are layer-lattice cation-exchangers that are of interest with respect to their applications in nuclear and hazardous wastewater treatment [1-3]. In 2015, the European Declaration on Paper Recycling reported that 71.5% of all paper consumed in Europe was recycled, corresponding to 1.2 million tonnes more than their 70% target [4]. Waste paper recycling ash (PRA) arising from this activity contains reactive calcium aluminosilicate phases that can be used for the hydrothermal synthesis of tobermorite when stoichiometrically adjusted with additional silicate-bearing reagents [1]. Waste soda-lime-silica container glass (SCG) has also been used as a partial feedstock for the preparation of tobermorite in alkaline media [2]. This research tested the feasibility of a one-step synthesis of tobermorite from a combination of PRA and SCG under alkaline hydrothermal conditions at 100 °C. Reaction products were analysed by powder X-ray diffraction (XRD) and scanning electron microscopy (SEM). This study also evaluated the Cs^+ cation-exchange capacity (CEC), selective Cs^+ distribution coefficients (K_d , from Na^+ and Ca^{2+} background solutions) and the uptake kinetics of Cd^{2+} and Pb^{2+} by the waste-derived tobermorite product.

2. Experimental – PRA (Aylesford Newsprint, Kent, UK) and SCG were ground to pass 250 μm . To prepare the tobermorite, 3.5 g of PRA, 3.5 g of SCG and 2.35 g of CaO were mixed with 60 cm^3 of 4 M $\text{NaOH}_{(\text{aq})}$, sealed in a PTFE autoclave and heated at 100 °C for 1, 2 and 5 days. Solid reaction products were separated by filtration, washed to pH ~8 with deionised water and dried in air at 60 °C prior to characterisation by XRD and SEM. Cs^+ CEC of the final 5-day tobermorite product was determined by the saturation of the ion-exchange sites with K^+ ions and their subsequent displacement by Cs^+ ions at 25 °C [1]. Cs^+ selectivity was evaluated by the uptake of Cs^+ from solutions having molar ratios $[\text{Cs}^+]:[\text{Na}^+]$ or $[\text{Cs}^+]:[\text{Ca}^{2+}]$ equal to 1:100 [1]. K_d values were calculated as the ratio of the amounts of Cs^+ sorbed and Cs^+ remaining in solution (in cm^3/g) [1]. Uptake kinetics of Cd^{2+} and Pb^{2+} were determined by exposure of 50 mg of tobermorite product to 200 cm^3 of 0.5 mM metal nitrate solution for up to 24 h [3]. All solutions were analysed by atomic absorption spectroscopy. All preparations and analyses were carried out in triplicate.

3. Results and Discussion - PRA comprises gehlenite ($\text{Ca}_2\text{Al}_2\text{SiO}_7$), åkermanite ($\text{Ca}_2\text{MgSi}_2\text{O}_7$), β -dicalcium silicate (Ca_2SiO_4), anorthite ($\text{CaAl}_2\text{Si}_2\text{O}_8$) and an amorphous silicate phase [1]. XRD analysis indicated that, during the hydrothermal reaction with SCG, the constituent mineral phases of PRA are progressively replaced by 11 Å tobermorite with hydrogarnet as a minor phase. SEM images confirmed that the product particles were in the size range 2 – 50 μm and displayed the typical foliaceous morphology of tobermorite. Cs^+ CEC of the tobermorite product was found to be 59 ± 4 meq/100g, and K_d values were 574 ± 13 and 658 ± 34 cm^3/g from Na^+ and Ca^{2+} background solutions, respectively. The sorption of Cd^{2+} and Pb^{2+} ions followed pseudo-second order kinetics with maximum uptake values of 130 ± 4 and 357 ± 7 meq/100g, respectively, at 24 h.

4. Conclusions - A candidate Cs^+ -selective tobermorite cation exchanger with a high uptake-capacity for Cd^{2+} and Pb^{2+} ions can be prepared by a facile one-step hydrothermal reaction between paper recycling ash and waste container glass.
