25 **Abstract**

26 **Aims:** Mild cognitive impairment (MCI) is a common complication of type 2 diabetes  
27 mellitus (T2DM). Changes in lifestyle and dietary patterns play a crucial role in  
28 preventing both diabetes and cognitive impairment.

29 **Methods:** A cross-sectional study was conducted on 899 aging participants. The  
30 Dietary Diversity Score (DDS) was used to evaluate dietary diversity. The physical  
31 activity (PA) levels were divided based on metabolic equivalents and weekly activity  
32 time. Individual PA levels were further re-scored and combined with DDS scores to  
33 obtain each participant's total score.

34 **Results:** Regardless of T2DM status, individuals with MCI had lower DDS and plant-  
35 derived DDS compared to non-MCI individuals. Non-MCI subjects had higher total PA  
36 and DDS scores than MCI subjects. There were differences in the correlation between  
37 DDS or PA scores and blood glucose and MoCA scores among different groups. The  
38 subjects with high DDS levels showed a significantly decreased risk of MCI and  
39 T2DM+MCI. Those with a total PA and DDS score in Q4 showed a significantly  
40 decreased risk of MCI and T2DM+MCI compared to Q1.

41 **Conclusions:** A diversified diet improved blood glucose levels and cognitive function.  
42 Elderly individuals with diverse diets and adequate PA had a reduced risk of developing  
43 T2DM and MCI.

44 **Keywords:** physical activity; dietary diversity; T2DM; MCI; combined effect

## 45 **1. Introduction**

46 Diabetes is a common chronic disease that seriously endangers the health of the middle-  
47 aged and elderly individuals. Abnormal blood insulin and glucose levels are the main  
48 pathological characteristics of diabetes (1). The global prevalence of diabetes among  
49 adults worldwide is 10.5%, and the number of diabetes patients is increasing with the  
50 aging of the population. According to data from the International Diabetes Federation  
51 (IDF10), it is estimated that by 2045, diabetes will affect 780 million people, with 90%  
52 diagnosed with type 2 diabetes mellitus (T2DM) (2). T2DM causes damage to various  
53 tissues and organs, including the brain, heart, kidneys, and eyes, leading to serious  
54 complications (3).

55 Alzheimer's disease (AD) is a progressive neurodegenerative disease caused by neuron  
56 damage, initially manifested as impaired memory and language abilities. Mild cognitive  
57 impairment (MCI) is the progression stage of AD. Subjects with MCI are at high risk  
58 of AD, with 50% of the MCI patients developing dementia within five years (4). In  
59 China, around 38.77 million elderly individuals suffering from MCI, which accounts  
60 for about 15.5% of the population aged 60 and above (5). Studies have found that  
61 diabetes is a risk factor for the development of cognitive dysfunction (6). Experimental  
62 animals and in vitro studies also demonstrated that oxidative stress or mitochondrial  
63 dysfunction in neurons caused by abnormal glucose metabolism promotes the  
64 pathology of AD (7). However, the accurate mechanisms of the increased risk of  
65 cognitive dysfunction in T2DM patients have not been fully clarified. There are still no  
66 effective treatments for cognitive dysfunction in T2DM individuals.

67 The effective role of physical activity (PA) in preventing noncommunicable chronic  
68 diseases has been extensively reported by previous studies (8). Leisure time PA (LTPA)  
69 reduces the risk of diabetes, and regular PA has been reported to decrease the risk of  
70 metabolic syndrome (9). PA-induced neural plasticity is important for enhancing  
71 cognitive function in the elderly with cognitive impairment (10). In contrast, prolonged  
72 sedentary behavior ( $\geq 3.03$  hours/day) increased the risk of developing MCI (HR =  
73 1.069,  $P < 0.05$ ) in the elderly (11).

74 Dietary Diversity Score (DDS) is an indicator used to evaluate the dietary pattern and  
75 the balance of an individual's dietary intakes (12). Research has found a negative  
76 correlation between DDS and healthy aging scores, indicating that dietary diversity is  
77 beneficial for the healthy aging process (13). Studies conducted in Britain and America  
78 indicated that a higher DDS correlated with a lower incidence of diabetes among adults  
79 (14). Additionally, consuming a greater variety of foods is associated with a  
80 significantly reduced risk of diabetes in Chinese adults (15). For the elderly, dietary  
81 diversity was recommended to alleviate cognitive dysfunction, especially in low-  
82 income or middle-income countries (16).

83 Numerous studies have explored the association of diets and PA on the risk of MCI and  
84 diabetes, but the combined effect of PA and dietary diversity on cognitive function in  
85 T2DM patients has rarely been reported. The present cross-sectional study was  
86 designed to explore the association of PA combined with dietary diversity with  
87 cognitive function in the elderly with T2DM. The aim is to provide a scientific basis  
88 for the formulation of integrated prevention strategies based on diet and PA for diabetic

90 **2. Methods**

91 **2.1 Subjects**

92 A total of 899 participants, including 287 males and 612 females, aged 55 to 75, were  
93 recruited from Nan Yuan Community Health Service Center in Beijing City (17). The  
94 study was conducted on participants who completed the dietary survey and cognitive  
95 function assessments. Individuals with the following conditions were excluded: (1)  
96 Brain tumors, (2) Parkinson's disease, (3) Other serious or unstable internal medicine  
97 diseases that can impact brain function or cognitive function evaluation, (4) With a  
98 history of acute cerebrovascular disease within 3 months, (5) Diagnosed with active  
99 epilepsy, (6) Diagnosed with dementia during the baseline survey, (7) Individuals with  
100 sensory impairment that prevents cognitive function tests, (8) With a history of mental  
101 illness (depression, mania, delirium, and anxiety). According to the diagnostic criteria  
102 for T2DM (2) and MCI (4). The subjects were divided into normal, T2DM, MCI, and  
103 T2DM combined with MCI (T2DM+MCI) groups. The study protocol was approved  
104 by the Committee on Medical Ethics of Capital Medical University (No. 2012SY23),  
105 and all procedures followed the ethical standards of the Helsinki Declaration of 1975.  
106 Informed consent was signed by all participants.

107 **2.2 Data Collection: Demographics, Dietary Survey, and Blood Sampling**

108 Survey questionnaires were used to collect basic demographic information, disease  
109 history, and family history. The lifestyle survey included PA levels (frequency of  
110 weekly physical activity, types of physical activities, and time for each activity) and  
111 smoking status. Body mass index (BMI) was classified as normal (18.5-23.9 kg/m<sup>2</sup>),

112 overweight ( $24-27.9 \text{ kg/m}^2$ ), and obesity ( $\geq 28 \text{ kg/m}^2$ ) according to the standard of the  
113 Chinese Nutrition Society (18). The Food Frequency Questionnaire (FFQ) (17) was  
114 used to investigate participants' daily dietary intakes. Educational level was defined as  
115 illiteracy, primary school level, secondary school and above based on self-report.  
116 The subjects were required to fast for 12 hours before blood sampling. Fasting venous  
117 blood was centrifuged (480g, 20 minutes), and plasma was separated. Plasma  
118 triglyceride (TG) was measured by ILAB600 clinical chemistry analyzer  
119 (Instrumentation Laboratory, Lexington, WI, USA). High-density lipoprotein  
120 cholesterol (HDL-C) was measured by an assay from the Instrumentation Laboratory  
121 (Lexington, WI, United States). Low-density lipoprotein cholesterol (LDL-C) was  
122 calculated according to the Friedewald formula (19).

### 123 *2.3 Physical activity level*

124 According to the classification criteria of the American Sports Association (20),  
125 Metabolic equivalent (MET) was used to evaluate PA levels. The daily PA intensity  
126 was classified as: (1) low intensity ( $< 3.0 \text{ METs}$ ), (2) moderate intensity ( $3.0-6.0 \text{ METs}$ ),  
127 and (3) high intensity ( $> 6.0 \text{ METs}$ ). Then calculate the weekly consumption of MET  
128 according to the formula:  $\text{MET minutes/week} = \text{MET value} \times \text{min/day} \times \text{day/week}$ .  
129 Classification criteria for PA level: (1) Highly active: High-intensity physical activity,  
130 at least 3 days per week and accrue at least 3000 MET minutes; or a combination of  
131 moderate to high-intensity activities at least 7 days/week and 3000 MET minutes. (2)  
132 Active: High-intensity PA for at least 3 days/week, accumulating at least 1500 MET  
133 minutes/week; or a combination of walking and moderate to high-intensity activities

134 totaling 3000 MET minutes/week. (3) Adequate: High-intensity PA for at least 3 days  
135 /week and at least 20 minutes/day; or engage in moderate-intensity PA or walking for  
136 at least 5 days/week and 30 minutes/day; or a combination of these activities totaling at  
137 least 600 MET minutes/week. (4) Deficiency: Not meeting the criteria for sufficient PA.  
138 (5) Sedentary behavior: No moderate or high-intensity PA during the week. In this  
139 study, highly active in the above criteria was defined as high-level PA; Active and  
140 adequate classified as moderate-level PA; Insufficient and sedentary were classified as  
141 low-level PA.

142 The criteria for PA score are as follows: (1) Frequency of weekly PA: everyday-3 points;  
143 4-6 days per week-2 points; 1-3 days per week-1 point; No physical activity-0 point. (2)  
144 Types of PA: Based on the self-report of the participants, each activity was scored 1  
145 point; if the frequency of PA was 0, this part will be scored 0 points; if individuals do  
146 not report specific activity types but have a weekly PA frequency of more than once a  
147 week, they will receive 1 point. (3) Time for each activity: < 30 minutes-1 point; 30-60  
148 minutes-2 points; more than 60 minutes -3 points. The total PA score was the sum of  
149 these three components.

#### 150 ***2.4 DDS scoring criteria***

151 According to the DDS scoring criteria (21) and the Chinese Dietary Guidelines for  
152 Residents (22), the 11 types of foods (including fruits, vegetables, grains, legumes, oils,  
153 fish, meat, nuts, beverages, milk and dairy products, eggs) in the dietary survey  
154 questionnaire were classified into 9 food groups: (1) Staple foods (grains, coarse grains),  
155 (2) Milk and dairy products, (3) Meat (fish and meat), (4) Fruits, (5) Vegetables, (6)

156 Legumes, (7) Eggs, (8) Oils (cooking oils and nuts), (9) Beverages. Among them,  
157 animal-derived foods including: (2) Milk and dairy products, (3) Meat (fish, meat), (7)  
158 Eggs. Plant-derived foods including: (1) Staple foods (grains, coarse grains), (4) Fruits,  
159 (5) Vegetables, (6) Legumes, (8) Oils.

160 The criteria of dietary intake scoring and DDS scoring were shown in table S1-2.

### 161 ***2.5 Cognitive function measurement***

162 The Montreal Cognitive Assessment Scale (MoCA) (22) was used to assess the  
163 cognitive function of the participants, which takes participants 15 minutes to complete.

164 Based on educational level, the critical points for diagnosing MCI were as follows:

165 13/14 for subjects without formal education, 19/20 for subjects with 1-6 years of  
166 education, and 24/25 for subjects with 7 years and above (23). These cutoff values have  
167 been validated as sensitive and effective for diagnosing MCI in the elderly population  
168 of China.

### 169 ***2.6 Statistical analysis***

170 SPSS 26.0 and R 4.2.2. were applied to perform statistical analysis. Quantitative data  
171 were expressed as mean  $\pm$  SD, and differences between groups were compared using t-  
172 tests, ANOVA analysis, general linear models, or rank sum tests. Categorical variable  
173 was expressed as number and percentage (n (%)), and  $\chi^2$  tests were applied to compare  
174 the differences between groups. Pearson or Spearman correlation was used to analyze  
175 the correlation between indicators. Logistic regression was used to analyze the effects  
176 of different levels of PA or DDS score, as well as the combined effects after quartiles  
177 of the total score on T2DM, MCI, and T2DM+MCI.  $P < 0.05$  was considered

178 statistically significant.

179 **3. Results**

180 **3.1 Demographic characteristics**

181 The subjects were divided into normal, T2DM, MCI, and T2DM combined with MCI  
182 (T2DM+MCI) groups according to the diagnostic criteria for T2DM (2) and MCI (4).

183 As shown in Table 1, the average age of patients with MCI and T2DM+MCI was higher  
184 than that of the normal group and T2DM group ( $P < 0.001$ ). In the MCI group, the  
185 proportion of males was lower than that in the T2DM group, but the opposite results  
186 were found in females ( $P = 0.048$ ). The education levels of the MCI group and  
187 T2DM+MCI group were significantly lower than that of the healthy normal group and  
188 T2DM group ( $P < 0.001$ ). Among the healthy group and T2DM group, there were more  
189 individuals with a high school education or above as compared to other groups ( $P <$   
190  $0.001$ ).

191 TG and fasting blood glucose levels in the T2DM and T2DM+MCI groups were  
192 significantly higher than those in the normal group and MCI population ( $P = 0.013$ ).

193 The serum HDL-C level in the T2DM and T2DM+MCI groups was significantly lower  
194 than that in the control and MCI group ( $P < 0.001$ ). The serum LDL-C level in the  
195 T2DM population was higher than the MCI group and T2DM+MCI group ( $P = 0.018$ ).

196 There was no significant difference in BMI, smoking habit, and blood TC levels among  
197 the groups ( $P > 0.05$ ) (Table 1).

198 **3.2 Comparison of cognition, DDS, and PA scores among groups**

199 We found that the total MoCA scores and cognitive domain scores in the MCI group  
200 and the T2DM + MCI group were lower than those in the normal and T2DM groups

201 (Table S3). Compared to the MCI group, the MCI+T2DM group showed poorer  
202 visuospatial & executive ability ( $P < 0.001$ , Table S3).

203 The DDS of the MCI group was lower than that of the normal and T2DM groups ( $P <$   
204  $0.001$ , Figure 1A). The DDS scores of plant-derived foods in healthy individuals and  
205 T2DM individuals were significantly higher than those in the MCI and T2DM+MCI  
206 patients ( $P < 0.001$ , Figure 1B). No significant difference in the DDS scores of animal-  
207 derived foods among different groups ( $P = 0.322$ , Figure S1D). And no significant  
208 difference in the total MET level, duration weekly, and PA score was observed among  
209 different groups ( $P_{MET} = 0.864$ ,  $P_{Time} = 0.867$ ,  $P_{PA\text{score}} = 0.794$ , Figure S1A-C). However,  
210 the total scores of DDS and PA were also higher in the healthy population and T2DM  
211 patients than in the MCI and T2DM+MCI group ( $P < 0.001$ , Figure 1C).

### 212 ***3.3 Relationship between PA levels, blood glucose, and cognitive function***

213 In the whole population, we observed a significantly negative correlation between  
214 blood glucose levels and MoCA scores ( $P < 0.05$ , Figure 2). This negative correlation  
215 was consistently observed in the MCI patients and the normal subjects, and a much  
216 stronger correlation was observed in the MCI patients ( $P < 0.05$ , Figure 2).

217 In the normal group, weekly MET and duration were negatively correlated with MoCA  
218 score ( $P < 0.05$ , Figure S2). The PA score was positively correlated with MoCA score  
219 in the whole population, MCI, and T2DM+MCI groups, but the opposite results were  
220 observed in the normal and T2DM groups ( $P < 0.05$ , Figure 2). Besides, there was a  
221 positive correlation between PA scores and orientation ability in each group ( $P < 0.05$ ,  
222 Figure 5A, Table S6).

223 We found a negative correlation between MET and blood glucose in the whole  
224 population ( $P < 0.05$ , Figure S2). Similarly, in the T2DM+MCI group, weekly MET  
225 and duration were negatively correlated with glucose level ( $P < 0.05$ , Figure S2).

### 226 ***3.4 Relationship between DDS scores, blood glucose, and cognitive function***

227 A positive correlation between DDS and MoCA score was observed in the whole  
228 population, normal, and the MCI groups ( $P < 0.05$ , Figure 2). DDS score positively  
229 correlated with the scores of naming ability in the whole population, MCI, and  
230 T2DM+MCI groups, and negatively correlated in the normal and T2DM groups ( $P <$   
231  $0.05$ , Figure 4A). The DDS score of animal-derived foods was negatively correlated  
232 with the MoCA score in the normal group ( $P < 0.05$ , Figure 3A). The DDS score of  
233 animal-derived foods was positively correlated with the scores of naming ability in the  
234 T2DM+MCI group, but a negative relationship was observed in other groups ( $P < 0.05$ ,  
235 Figure 3A). The DDS score for plant-derived foods was positively correlated with  
236 MoCA scores and language in all groups ( $P < 0.05$ , Figure 3A). The DDS score for  
237 plant-derived foods positively correlated with memory and abstraction in the whole  
238 population, MCI, and T2DM+MCI groups, but a negative relationship was observed in  
239 the T2DM group. And in the normal group, the DDS score for plant-derived foods was  
240 positively correlated with memory ability but negatively correlated with abstraction  
241 ability ( $P < 0.05$ , Figure 3A).

242 A negative correlation between DDS score and glucose level was found in the whole  
243 population ( $P < 0.05$ , Figure 2). In the normal, T2DM, and MCI groups, the DDS score  
244 also significantly negatively correlated with blood glucose levels ( $P < 0.05$ , Figure 2).

245 The DDS score of plant-derived foods negatively correlated with blood glucose level  
246 in the normal, MCI, and T2DM groups ( $P < 0.05$ , Figure S3), but no relation was  
247 observed in the T2DM+MCI group.

### 248 ***3.5 The relationship between food intake, blood glucose, and cognitive function***

249 Participants in the T2DM and T2DM+MCI groups have lower daily fruit intake than  
250 other groups ( $P < 0.001$ , Table S4). The vegetable intake in the T2DM and normal  
251 groups was higher than that in the T2DM+MCI group ( $P = 0.017$ , Table S4). The daily  
252 intake of fruits and vegetables was positively correlated with naming ability in all  
253 participants, T2DM, and T2DM+MCI groups ( $P < 0.05$ , Figure 3B). However, in the  
254 normal group, daily fruit intake positively correlated with naming ability, while  
255 vegetable intake negatively correlated with naming ability. In the MCI group, daily fruit  
256 intake negatively correlated with naming ability, while vegetable intake positively  
257 correlated ( $P < 0.05$ , Figure 3B).

258 Variability in the correlation between daily legume intake and cognitive function was  
259 observed among groups. Specifically, in the entire population, the intake of legumes  
260 positively correlated with MoCA score, and scores in language, abstraction, and  
261 memory domains ( $P < 0.05$ , Figure 3B). In the normal group, legume intake negatively  
262 correlated with MoCA score, and abstraction and memory abilities, but positively  
263 correlated with language ability ( $P < 0.05$ , Figure 3B). In the T2DM group, daily  
264 legume intake positively correlated with MoCA score, language, and memory abilities,  
265 but negatively correlated with abstraction ability ( $P < 0.05$ , Figure 3B). In the MCI  
266 group, the intake of legumes positively correlated with MoCA score, language, and

267 abstraction abilities, but negatively correlated with memory ability. In the T2DM+MCI  
268 group, legume intake positively correlated with MoCA score, and abstraction and  
269 memory abilities, while negatively correlated with language ability ( $P < 0.05$ , Figure  
270 3B).

271 In the normal group, daily cooking oil consumption negatively correlated with MoCA  
272 score, but positively correlated with orientation ability ( $P < 0.05$ , Figure 3B). In the  
273 T2DM group, daily cooking oil consumption negatively correlated with MoCA score  
274 and orientation ability ( $P < 0.05$ , Figure 3B). In the other groups, daily cooking oil  
275 consumption positively correlated with total MoCA score, but negatively correlated  
276 with orientation ability ( $P < 0.05$ , Figure 3B).

### 277 ***3.6 Association of PA, dietary diversity with cognition***

278 As shown in Table S8 and Figure 4A, no relationship was observed between PA and  
279 the risk of T2DM, MCI, and T2DM+MCI. The association between DDS level and the  
280 risk of T2DM was not found in our study. However, a significant negative correlation  
281 was detected between DDS level and the risk of MCI and T2DM+MCI. In Model 1,  
282 compared with subjects with a low DDS level, those with a high DDS level showed a  
283 significantly decreased risk of MCI (OR = 0.565, 95% CI: 0.423-0.753) and  
284 T2DM+MCI (OR = 0.680, 95% CI: 0.515-0.899) respectively ( $P < 0.05$ ). After  
285 adjusting for age, TG, HDL-C, and LDL-C, a high DDS level remained a protective  
286 factor for decreasing the risk of MCI and T2DM+MCI ( $OR_{MCI} = 0.586$ , 95% CI: 0.432-  
287 0.795,  $P = 0.001$ ;  $OR_{T2DM+MCI} = 0.701$ , 95% CI: 0.522-0.940,  $P = 0.018$ ). In Model 3,  
288 when further adjusting for gender and education level, the correlation between DDS

289 level and the risk of T2DM+MCI became nonsignificant ( $P = 0.123$ ) (Table S8, Figure  
290 4A).

291 As shown in Table S9 and Figure 4B, the total scores of DDS and PA were divided into  
292 four quartiles: Q1 (score  $\leq 16$ ), Q2 ( $17 \leq \text{score} \leq 18$ ), Q3 ( $19 \leq \text{score} \leq 20$ ), Q4 (score  
293  $\geq 21$ ). The results of logistic regression showed that, in Model 1, the subjects with Q4  
294 level of total PA and DDS score have a lower risk of T2DM than those with Q1 level  
295 of total PA and DDS score ( $OR = 0.855$ , 95% CI: 0.542-1.348,  $P < 0.05$ ), and this  
296 protective effect disappeared after adjusting for confounding factors in Model 2 and  
297 Model 3 ( $P > 0.05$ , Table S9). A negative correlation between total PA and DDS score  
298 on the risk of MCI was detected. Compared with the population with Q1 ( $\leq 16$  points)  
299 level of total PA and DDS score, the risk of MCI was reduced in subjects with Q3 and  
300 Q4 ( $\geq 19$  points) levels ( $OR_{Q3} = 0.594$ , 95% CI: 0.405-0.870,  $P = 0.007$ ;  $OR_{Q4} = 0.369$ ,  
301 95% CI: 0.239-0.569,  $P < 0.001$ ). After adjusting for confounding factors, the  
302 protective role of high total PA and DDS score on the risk of MCI was consistently  
303 observed ( $P < 0.05$ ). We also found that the increase of total PA and DDS score  
304 decreased the risk of T2DM+MCI. And the participants with Q4 level of total PA and  
305 DDS score showed a significantly decreased risk of T2DM+MCI as compared with  
306 subjects with Q1 level ( $OR = 0.507$ , 95% CI: 0.337-0.762,  $P = 0.001$ ). And the  
307 protective effect still exists after adjusting for confounding factors in Model 2 and  
308 Model 3 (Model 2:  $OR = 0.538$ , 95% CI: 0.353-0.819,  $P = 0.004$ ; Model 3:  $OR = 0.625$ ,  
309 95% CI: 0.407-0.959,  $P = 0.032$ , Figure 4B).

#### 310 **4. Discussion**

311 In this research, we established a link between PA and dietary diversity and their impact  
312 on the risk of T2DM, MCI, and the combined condition of T2DM+MCI in older adults.  
313 The cognitive impairment of T2DM patients was related to impaired glucose  
314 metabolism and insulin dysfunction (24). Consistent with the result, we demonstrated  
315 a negative correlation between blood glucose and MoCA score, suggesting that  
316 abnormal glucose metabolism might increase the risk of MCI in T2DM patients.  
317 Moreover, abnormal cell apoptosis, oxidative stress, impaired insulin signaling,  
318 neuroinflammation, and impaired synaptic function were potential mechanisms of  
319 cognitive dysfunction in T2DM patients (24).

320 In the present study, a negative correlation between blood glucose level and total  
321 weekly MET value, as well as the duration of PA, was detected. Similarly, previous  
322 studies have shown that PA has a positive effect on the progression of T2DM. Thirty  
323 minutes of moderate to high-intensity PA per day was associated with lower all-cause  
324 mortality, regardless of diabetes status (25). In patients with impaired blood glucose  
325 and prediabetes, acute stair-climbing reduced postprandial blood glucose concentration  
326 (26). Besides, the data from randomized controlled trial research further demonstrated  
327 that the T2DM patients who underwent 12 weeks of PA intervention showed a  
328 significant decrease in blood glycated hemoglobin (27), suggesting the efficiency of  
329 PA in controlling diabetes symptoms.

330 To date, discrepant conclusions have been derived from studies regarding the  
331 relationship between PA with cognition in the elderly. One study found that MCI  
332 patients have a longer sedentary time and engage in less moderate to high-intensity PA

333 compared to control subjects (28). A population-based epidemiological study also  
334 demonstrated that the MoCA score was positively correlated with the physical activity  
335 level in the elderly, while sedentary time was positively correlated with  
336 visuospatial/executive abilities (29). In our study, the correlation between PA score and  
337 cognition was consistent with the findings from previous studies in the entire population  
338 and MCI patients. No difference was observed in the weekly MET value and duration  
339 among the groups. Similarly, others have also reported that there is no correlation  
340 between physical activity and cognitive performance in the elderly (30).

341 Interestingly, physical activity was weakly negatively correlated with cognition in the  
342 normal and T2DM groups. Due to the unknown nonphysical activities among  
343 participants, we cannot determine whether the participants engaged in cognitive  
344 exercises (such as social contact and mental games), which could be a factor affecting  
345 the relationship between PA and cognitive performance. Previous studies have  
346 confirmed that a high level of education is a protective factor for cognitive dysfunction  
347 (31). Consistently, we confirmed that compared to the MCI patients, the subjects from  
348 the normal and T2DM groups have a relatively higher education level. Additionally, it  
349 has been reported that T2DM patients have an increased risk of hearing loss compared  
350 to normal individuals, and hearing impairment might be another potential modifying  
351 factor on PA in the elderly, especially in terms of body balance ability. More severe  
352 hearing loss further impacts daily PA and exercise, such as long-distance running (32).  
353 Research has shown that three months of aerobic training improves naming ability in  
354 AD patients (33). Study conducted in the elderly Chinese adults indicated that Tai Chi,

355 dancing, and basketball have displayed a significant improvement effect on cognitive  
356 function, and Tai Chi is the best PA and should be recommended to the elderly to  
357 prevent cognitive decline (34). These data suggest that the association between PA and  
358 cognitive function might be the PA type-dependent. Therefore, when exploring the  
359 relationship between PA and cognition, the type of physical activity should be taken  
360 into consideration, as well as leisure activities during sedentary periods.

361 The protective role of diversified diets in improving cognitive function and maintaining  
362 stable blood glucose has been reported by previous study (35). A study conducted in  
363 China found that people with high DDS scores have a decreased risk of cognitive  
364 impairment (36). DDS levels are positively correlated with overall cognitive function,  
365 memory, attention, language fluency, and executive function in elderly people (37).  
366 These results are highly consistent with our findings. Our data also demonstrated that  
367 in the whole population and MCI patients, participants with higher DDS score displayed  
368 higher cognitive score than subjects with lower DDS scores, especially in the naming  
369 domain.

370 DDS score was negatively correlated with blood glucose levels in our study. Although  
371 a meta-analysis showed that the correlation between DDS score and diabetes was not  
372 statistically significant (38), consistent with our results, a community population-based  
373 study conducted in Thailand demonstrated that DDS was significantly negatively  
374 correlated with the risk of diabetes (39). We found that people with higher DDS scores  
375 have a lower risk of developing T2DM+MCI, which is 0.789 times that of those with  
376 lower levels of DDS. T2DM patients are characterized by insulin dysfunction, leading

377 to abnormal blood glucose level, which is a critical cause of cognitive impairment (40).  
378 The progression of diabetes complications may be modified by improving glyceemic  
379 control (41). The study found that participants with a diverse diet often have lower  
380 glucose level and there is a significant negative correlation between blood glucose and  
381 MoCA score. A previous study demonstrated that reduced risk of developing AD or  
382 MCI was commonly observed in the T2DM patients with better glyceemic control (42).  
383 Our data infer that a diversity diet could improve the symptoms of diabetes and  
384 cognitive function by ensuring reasonable micro- and macro- nutrients intakes and  
385 regulating blood glucose homeostasis in T2DM patients.

386 It was reported that maintaining a high level of DDS could alleviate cognitive decline,  
387 and the dynamic changes of DDS are reported to correlate with cognitive decline (43).  
388 Compared with those who maintain a stable DDS, individuals with moderate or above  
389 decline of DDS have an elevation in the risk of cognitive decline (44). Another  
390 community-based prospective study also confirmed that maintaining a high level of  
391 DDS or improving DDS can reduce the risk of cognitive impairment in older adults  
392 (45). A higher DDS score is always accompanied by a better cognitive level (45), but  
393 dietary changes may take many years to reduce the risk of dementia (46). Therefore,  
394 maintaining a high level of DDS for a long period, ensuring dietary diversity, and  
395 consuming various food items are conducive to improving cognitive level in the elderly.

396 In our study, the dietary pattern of the T2DM population was characterized by lower  
397 daily fruit intake and higher vegetable intake. Compared with T2DM subjects, lower  
398 vegetable intake and DDS scores of plant-derived foods were shown in the population

399 combined with MCI. Fruits are commonly substantial sources of fructose, and fructose  
400 metabolism potentially decreases insulin sensitivity and elevates risk factors for T2DM  
401 (47). Thus, T2DM patients might be prone to limit their daily intake of fruits.  
402 Vegetables are rich in dietary fiber and various phytochemicals, which could help to  
403 control blood glucose. T2DM individuals are commonly advised to consume more  
404 green leafy vegetables (48). However, this study cannot determine whether the patients  
405 adjusted their dietary pattern or underwent diet management after the clinical diagnosis  
406 of T2DM, which might potentially modify their food choice and dietary habits. In China,  
407 a dietary pattern rich in fruits, vegetables, red meat, fish, eggs, beans, nuts, and milk  
408 can reduce the risk of cognitive impairment (49). Partly consistent with this study, we  
409 also found a positive correlation between DDS score for plant-derived foods and  
410 cognitive function, but a different relationship in food types. Our data demonstrated  
411 that cognitive function was negatively correlated with animal-derived foods and  
412 positively correlated with plant-derived foods, suggesting the importance of optimal  
413 food choice for the elderly to protect cognition.

414 Overall, our research indicated that plant-derived foods, including fruits, vegetables,  
415 legumes, and cooking oils, play a preventive role in reducing cognitive decline among  
416 individuals with T2DM. However, T2DM patients should monitor their consumption  
417 of cooking oils. For patients with chronic diseases such as T2DM and MCI, adjusting  
418 their dietary pattern and customizing dietary combinations according to dietary  
419 guidelines could help maintain glucose stability and improve cognitive function (27).  
420 For healthy individuals, although our data revealed a negative correlation between

421 certain foods and cognitive function, the complexity of diets made us speculate that  
422 the contribution of different foods and nutrient combinations to cognitive function was  
423 overwhelming. Therefore, it is necessary to comprehensively explore the role of dietary  
424 patterns and food diversity in affecting cognition in the elderly in the future.

425 To investigate the combined effects of diverse diets and physical activities on cognitive  
426 function, we used the total score of PA and DDS to analyze their impact on the risk of  
427 T2DM and MCI. As expected, a high total DDS and PA score significantly reduce the  
428 risk of T2DM and MCI in older adults. Similarly, for T2DM or MCI populations, a  
429 variety of diets and sufficient physical activity could decrease the risk of the diseases,  
430 especially in the subjects with the total score of PA and DDS greater than 21. Moreover,  
431 we found that DDS was a protective factor for MCI and T2DM+MCI, while this  
432 protective role on T2DM was only observed when analyzing the combined effects,  
433 suggesting the potential interaction between a reasonable diet and PA in affecting health  
434 outcomes in the elderly. The accurate mechanism through which diet diversity and PA  
435 exhibit a cognitive protective effect is still unclear. Studies have found that PA and  
436 dietary intervention, psychological or social behavior intervention were efficient in  
437 improving the physical function of the elderly and promoting healthy aging (50).  
438 Therefore, it is necessary to conduct a population-based large-scale cohort study to  
439 uncover the mechanism of diet diversity and PA on cognition in the elderly.

440 There are some limitations in this study. Firstly, the cross-sectional study design made  
441 us fail to dynamically monitor the changes in lifestyle habits, blood glucose, and  
442 cognition of the elderly, resulting in the lack of ability to infer causality, so longitudinal

443 studies are necessary for future research. Secondly, although some confounding factors  
444 were adjusted during data analysis, considering the small sample size of our study, some  
445 unknown confounding factors might potentially affect our conclusion; therefore, large-  
446 scale perspective studies are expected. Lack of more detailed data on the type of  
447 physical activity is another limitation of this study, which was also the possible reason  
448 for us failing to observe the relation between physical activity and cognitive function.  
449 Therefore, the survey of physical activity type is strongly recommended for exploring  
450 the relation between physical activity and cognitive function in the elderly.

451 **5. Conclusions**

452 Our findings indicate that: (1) T2DM patients with a diversified diet showed lower  
453 blood glucose levels but higher cognitive function than normal; (2) The elderly with  
454 diverse diets and adequate physical activity have a decreased risk of developing T2DM  
455 and MCI. Elderly people with T2DM should ensure the intake of varied food items and  
456 selectively consume more plant-based foods. Adequate physical activity while  
457 consuming high-quality meals is beneficial for controlling blood glucose levels in  
458 T2DM patients. A combined intervention strategy integrating diet and physical activity  
459 might have much greater health benefits for T2DM and MCI prevention in the elderly.

652 The table shown the correlation coefficients between the two variables. Using Pearson correlation or Spearman correlation analysis,  $P < 0.05$  indicates a statistically  
653 significant difference. T2DM, type 2 diabetes mellitus; MCI, mild cognitive impairment; MoCA, Montreal Cognitive Assessment. PA, Physical activity; MET,  
654 Metabolic equivalent; DDS, Dietary diversity scores; Total score included and PA score.

**Table S7 Correlation matrix between food intake and cognitive function in groups**

| Cognitive function        | Fruit   | Vegetable | Legume  | Cooking oil | Fish    | Whole grain | Red meat | Light meat | nut     | milk    | egg     |

656 The table shown the correlation coefficients between the two variables. Using Pearson correlation or Spearman correlation analysis,  $P < 0.05$  indicates a statistically  
657 significant difference. T2DM, type 2 diabetes mellitus; MCI, mild cognitive impairment; MoCA, Montreal Cognitive Assessment. PA, Physical activity; MET,  
658 Metabolic equivalent; DDS, Dietary diversity scores; Total score included and PA score.

**Table S8 Association of PA and DDS with T2DM, MCI and T2DM+MCI in the elderly**

660 Logistic regression was applied to analyze the relation between physical activity and DDS with T2DM, MCI and T2DM+MCI in the elderly. In Model 1, no confounding  
661 factors were adjusted; In Model 2, confounding factors including age, TG, HDL-C, and LDL-C were adjusted; In Model 3, based on model 2, confounding factors  
662 including gender and education level were adjusted.  $P < 0.05$  indicates a statistically significant difference. T2DM, type 2 diabetes mellitus; MCI, mild cognitive  
663 impairment; TG, triglyceride; HDL-C, high-density lipoprotein cholesterol; LDL-C, low-density lipoprotein cholesterol; DDS, Dietary diversity scores, PA, Physical  
664 activity.

666 Logistic regression was applied to analyze the relation between total score of physical activity and DDS with T2DM, MCI and T2DM+MCI in the elderly. Total score  
667 included and PA score Q1: score  $\leq 16$ ,  $N = 250$ ; Q2:  $17 \leq \text{score} \leq 18$ ,  $N = 301$ ; Q3:  $19 \leq \text{score} \leq 20$ ,  $N = 194$ ; Q4: score  $\geq 21$ ,  $N = 154$ . In Model 1, no confounding  
668 factors were adjusted; In Model 2, confounding factors including age, TG, HDL-C, and LDL-C were adjusted; In Model 3, based on model 2, confounding factors  
669 including gender and education level were adjusted.  $P < 0.05$  indicates a statistically significant difference.  $P < 0.05$  indicates a statistically significant difference.  
670 T2DM, type 2 diabetes mellitus; MCI, mild cognitive impairment; DDS, Dietary diversity scores, PA, Physical activity.

671 **Figures**

672

673 Figure 1 Raincloud plots of DDS and total score for each group of people.

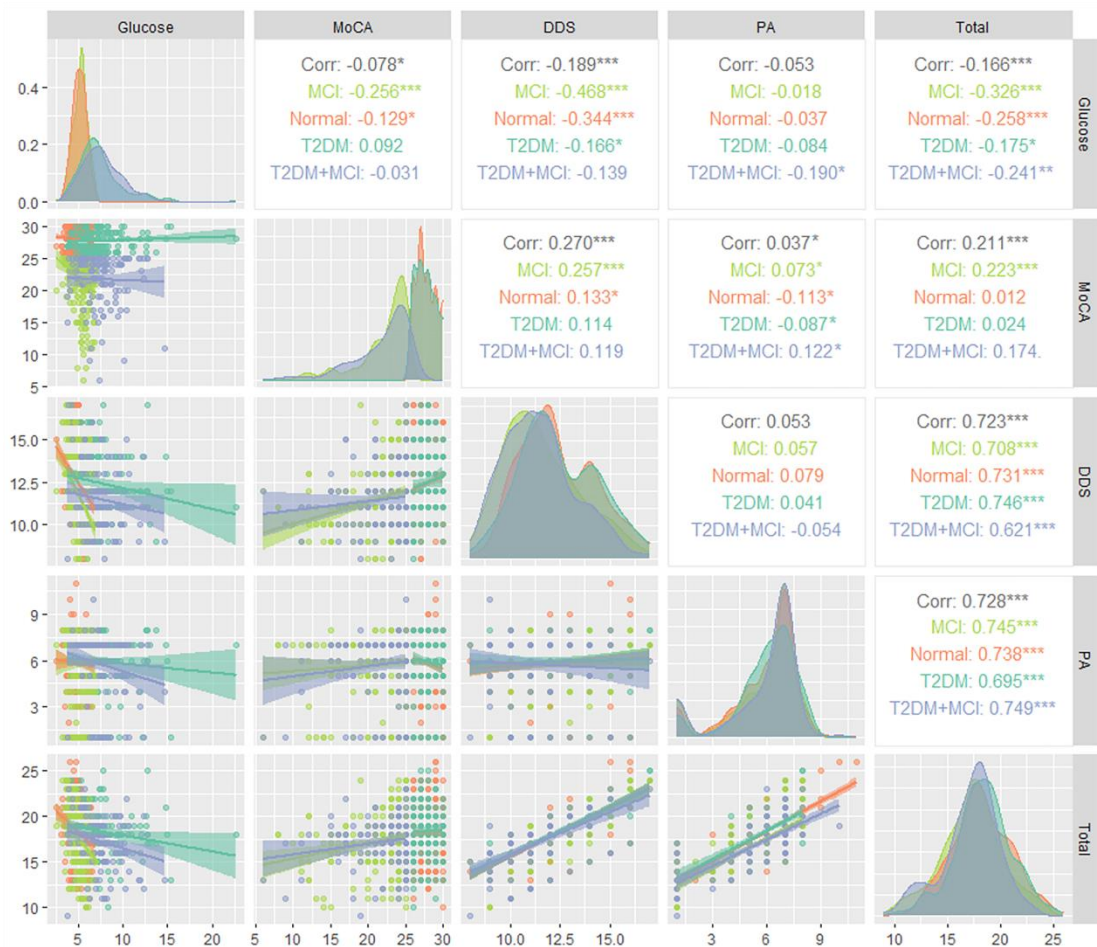

674 (A) DDS; (B) DDS of plants derived foods; (C) Total score includes DDS and PA score.

675 T2DM, type 2 diabetes mellitus; MCI, mild cognitive impairment; PA, Physical activity;

676 DDS, Dietary diversity scores. \*: The differences are statistically significant compared

677 with the normal and T2DM group,  $P < 0.05$ .

678

679

680 Figure 2 Correlation heatmap between MoCA, glucose, DDS, PA score and total score  
 681 among different groups.

682 T2DM, type 2 diabetes mellitus; MCI, mild cognitive impairment; MoCA, Montreal  
 683 Cognitive Assessment; PA, Physical activity; DDS, Dietary diversity score, total score  
 684 includes DDS and PA score. \*: There is a statistically significant relationship between  
 685 two variables,  $P < 0.05$ ; \*\*: There is a statistically significant relationship between two  
 686 variables,  $P < 0.01$ ; \*\*\*: There is a statistically significant relationship between two  
 687 variables,  $P < 0.005$ .

688  
 689 Figure 3 Heat map.

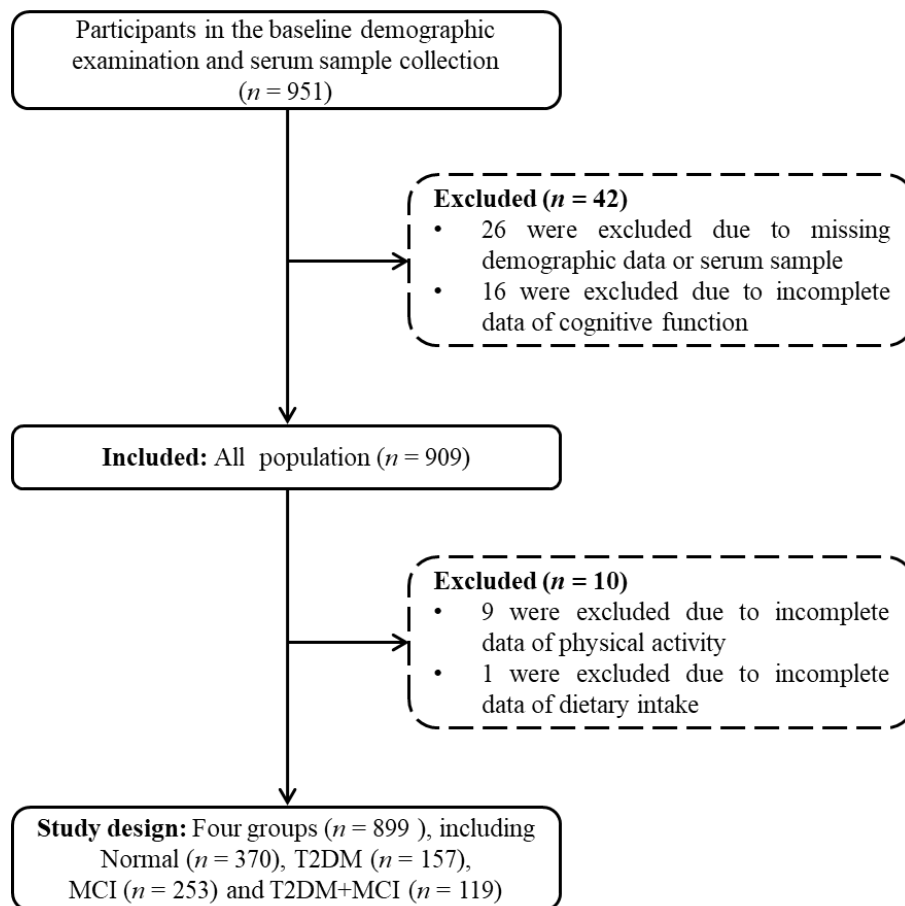

690 (A) Heat map of the correlation between glucose, DDS, physical activity level, MoCA  
 691 score, and cognitive domains in each group; (B) Heat map of the correlation between  
 692 different types of food intakes, blood glucose, MoCA score, and cognitive domains in  
 693 each group. T2DM, type 2 diabetes mellitus; MCI, mild cognitive impairment; MoCA,  
 694 Montreal Cognitive Assessment; MET, Metabolic equivalent; DDS, Dietary diversity

695 scores; PA, Physical activity. \*: There is a statistically significant relationship between  
 696 two variables,  $P < 0.05$ ; \*\*: There is a statistically significant relationship between two  
 697 variables,  $P < 0.01$ ; \*\*\*: There is a statistically significant relationship between two  
 698 variables,  $P < 0.005$ .

701 Figure 4 Logistic regression.  
 702 Logistic regression was applied to analyze the relation between physical activity level,  
 703 DDS score(A)and total score(B) with T2DM, MCI and T2DM+MCI in the elderly. In  
 704 Model 1, no confounding factors were adjusted; In Model 2, confounding factors  
 705 including age, TG, HDL-C, and LDL-C were adjusted; In Model 3, based on model 2,

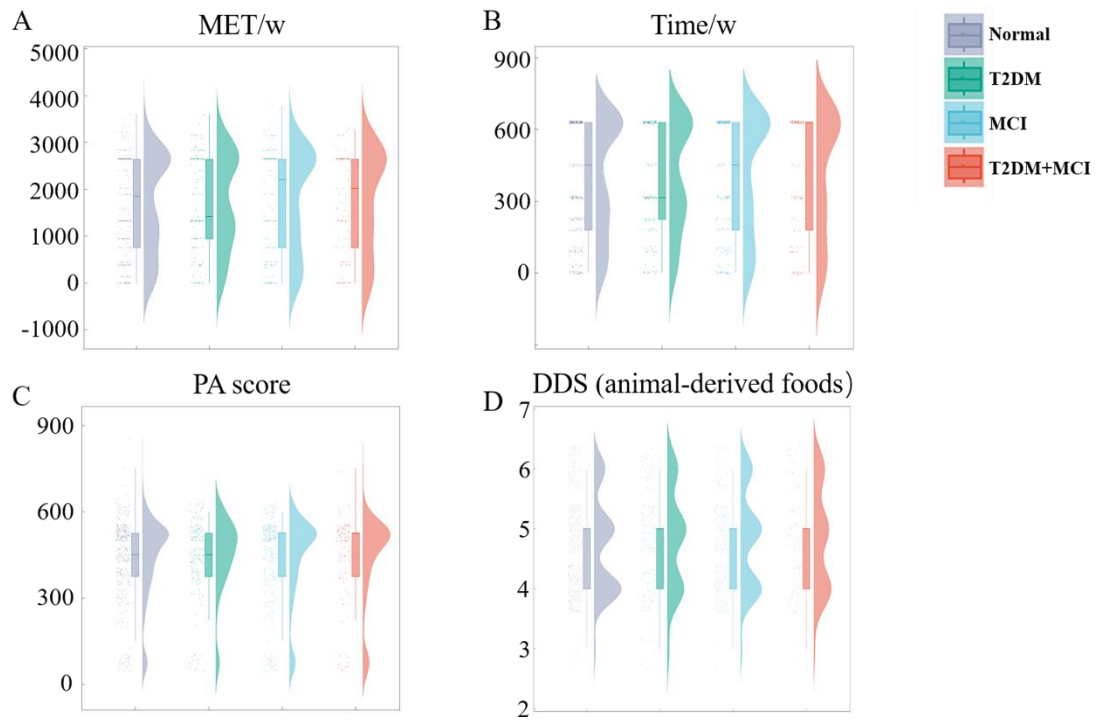

706 confounding factors including gender and education level were adjusted.  $P < 0.05$   
 707 indicates a statistically significant difference. T2DM, type 2 diabetes mellitus; MCI,  
 708 mild cognitive impairment; TG, triglyceride; HDL-C, high-density lipoprotein  
 709 cholesterol; LDL-C, low-density lipoprotein cholesterol; DDS, Dietary diversity scores.  
 710 Total score included and PA score, Q1: score  $\leq 16$ ,  $N = 250$ ; Q2:  $17 \leq \text{score} \leq 18$ ,  $N$   
 711  $= 301$ ; Q3:  $19 \leq \text{score} \leq 20$ ,  $N = 194$ ; Q4: score  $\geq 21$ ,  $N = 154$ .
